Kliebard is arguably the leading practitioner of historical research in curriculum studies in the last quarter century. He has published numerous volumes in which he outlines a variety of approaches to the school curriculum in 20th-century education. Although he certainly discusses more than classical and anticlassical emphases in various school curricula, it is also the case that his work can best be seen as an expansion and complication of the classical–anticlassical dichotomy rather than a rejection of it.

Turning now to the topic of progressive education as a curricular phenomenon in schools, the presence of Dewey as a founder, if not a director, of progressive curricula must be acknowledged. What also must be acknowledged, however, is Dewey's critique of progressive approaches and programs that abandoned subject matter for the sake of alternatives that catered to immediate student interest. Dewey claimed to occupy a middle ground between traditionalists and progressives, one that acknowledged the primacy of both student interest and subject matter. The proper marriage of these two emphases, for Dewey, came in the productive encounter of students whose interest was piqued by subject matter that furthered those interests, both of which came from the efforts of skilled teachers committed to genuine student learning.

Of course, historical research into curriculum has involved more than looking at Dewey. Recent works have focused on the serious innovations sponsored by progressive educators in the 1930s and 1940s such as those grouped under the rubric of the Eight Year Study. Most recently, Craig Kridel and Robert Bullough have provided a comprehensive and sensitive analysis of the Eight Year

Study. Their work has shown how the innovative schools that participated in the Eight Year Study embodied creative approaches to curriculum innovation. They also have shown how the efforts of these schools were subject to friendly, but rigorous evaluation by scholars led by Ralph Tyler, then of the Ohio State University and later of the University of Chicago. Tyler became a giant in the field of curriculum studies through his Eight Year Study work and his other work on curriculum development and evaluation.

Shortly after the Eight Year Study ended, really almost contemporaneous with it, a less rigorous version of curriculum innovation was proffered in the work of life adjustment educators such as Charles Prosser. Life adjustment advocated an approach to education, especially high school education, that if it did not abandon academic study, made it secondary in significance to nonacademic tasks seen as necessary to reach the clear majority of students who were attending the high school. Prosser divided the high school population into a small portion of students who could profit from academic study, another small portion who could flourish in vocational studies, and the substantial majority that represented neither of these orientations and needed lessons in various life activities and orientations as the major outcome of their time in school.

Not surprisingly, life adjustment received a scathing critique from academics in U.S. colleges and universities who saw it as a waste of time and a markedly inferior alternative to rigorous academic study in secondary schools. These academic critics found a fertile audience in many strata of U.S. public opinion, and they enthusiastically offered their own academic curricular alternatives for high school courses, particularly though not exclusively in science and mathematics. Their efforts to develop high school courses in physics, mathematics, and the other sciences were quickly echoed in nonscience fields, and the entire movement to have school studies dependent on, if not designed by, academics was given momentum in a psychological study produced by Jerome Bruner, a noted Harvard psychologist. Bruner argued that any subject could be studied intellectually in schools in a way analogous to that which it was approached by scholars in higher education.

A classic analysis of the U.S. high school by retired Harvard president James Bryant Conant in 1958 managed to support both academic and vocational alternatives to academics through its advocacy of the comprehensive high school. Seeing this institution as dominant in small cities, Conant tried to indicate how its curricular diversity might be incorporated in other settings. He was particularly impressed with how the comprehensive high school allowed both academic education and preparation for work to take place, without separating the two groups of students from each other completely. Conant, who participated in the preparation of the progressive landmark treatment of high schools at the end of World War II, *Education for All American Youth*, also was influenced by his own academic background as a chemist and was conversant with the scientists who embarked on serious reform of high school science courses, as well as with other academic critics of progressive approaches to the high school such as the noted historian Arthur Bestor. Rigorous analysis of Conant's ideas, as well as his enormous influence in U.S. educational policy and practice, awaits a contemporary historian bold enough to attempt that task.

The critique of academic education by life adjustment educators and the academic reaction to it have been echoed in many recent histories of various aspects of the curriculum. Most of these historians have excoriated life adjustment as well as other nontraditional approaches to the school curriculum and defended academic studies as the major, if not the only, focus of the school curriculum. Diane Ravitch has produced several works in this vein, and her antiprogressive argument has been echoed, actually improved upon, in works such as the book on high school course taking by David Angus and Jeffrey Mirel.

Progressivism and antiprogressivism have not been the only focus of historians of the curriculum. Some, such as Barry Franklin, have looked at the genesis of special education in the early 20th century and its evolution to the point in contemporary education that it occupies an enormous place in the school curriculum. Franklin and others have shown how special education has attempted to fulfill student needs at the same time that it has been boosted by the bureaucratic orientations of school systems and the democratic purpose, and bureaucratic reach, of federal legislation.

### College and University Curriculum

The final task in this entry is to turn to a brief look at historical work on the college and university curriculum. One comprehensive volume on the topic produced by the noted historian of U.S. higher education Frederick Rudolph chronicled the rise and fall of the classics in the college curriculum and the various studies that have superseded the classics. Notable institutionally in this saga is the rise of the land grant colleges in the middle and late 19th century and the development of various kinds of professional education subsequently. Although education for the traditional professional troika of clergy, law, and medicine took place alongside of classical university studies, education for newer professions such as engineering, social work, education, and many others has placed the professional curriculum directly in competition with, if not in direct conflict with, the classics and the various academic studies grouped under the label of liberal arts or liberal education that have succeeded the classics.

In the midst of these developments, college and university curriculum has been the arena for great debates over the content of general education, the first 2 years of undergraduate study, and what to do with these years and these studies in a time of increasing intellectual specialization and curricular diversification. The variety of curriculum experiments that have been undertaken to revitalize liberal and general education, particularly in the 20th century, have provided historians and other analysts of college and university curricula with ample examples of how to maintain, improve, or replace liberal studies with other approaches that simultaneously meet the needs of student interest and the requirements of intellectual acuity in a changing society.

### Future Research

Thus we return to the ideas that have animated the historical study of school curricula. The intellectual rigor of classical studies and the academic alterations that they have undergone stand on one end of a curricular continuum. On the other end stand the vocational, professional, and other non-academic studies that appeal intuitively to most students at any level of education and to many of those who study curriculum. It is perhaps overly optimistic to conclude that future historical research in curriculum studies might add creatively to both

the analysis and advocacy of both of these curricular strands. More important, perhaps, will be the studies that creatively look at the combinations of the two approaches that have been productive. These will represent the historical embodiment of Dewey's intellectual insight that the best education, in schools as well as in colleges and universities, is properly attentive both to academic interests and to utilitarian concerns such as student interest and societal improvement.

## HOLISTIC CURRICULUM

---

Holistic curriculum is a description of educational practices intended to cultivate fully developed human beings by attending to their physical, emotional, psychological, moral, and spiritual growth. Cultivation of personal meaning and fulfillment, love for lifelong learning, and connection to others and the natural world are among educators' aims in the holistic curricular tradition.

Holism, in this curricular orientation, means both oneness and interrelatedness. Advocates of this curriculum disavow common dualisms—such

as mind–body, logic–intuition, art–science, or group–individual. They also reject the fragmentation, standardization, and competition of modern society and schooling so that individuals can develop without experiencing systems that limit or stifle their growth and potentials. Moreover, holism entails recognizing the interconnectedness of the universe, including all of life and nature.

Educators began to refer to the term *holistic curriculum* in the late 1970s, and this designation became established with Ron Miller’s publication of the *Holistic Education Review* in 1988 and John P. Miller’s book, *The Holistic Curriculum*, published in the same year. Nonetheless, the intellectual foundation of holistic curriculum has been attributed to the Platonic ideal of a well-balanced education of intellectual, physical, and spiritual development and to 19th-century and early 20th-century child-centered theorists and educators including Jean-Jacques Rousseau, Johann Heinrich Pestalozzi, Friedrich Wilhelm Froebel, Francis Parker, and A. S. Neill. More contemporary influences on holistic curriculum are the open school movement of the 1960s and 1970s and works by Richard Jones, *Fantasy and Feeling in Education*, and Joseph Chilton Pearce, *The Magical Child*. Montessori and Waldorf schools are viewed as both antecedent and contemporary models of holistic curriculum. In addition, other curricular models—experiential, whole person, self-directed, peace, global, and ecological—feature parallels to holistic curriculum.

Although holistic curricular practices vary, for instance, to the extent of emphasis on practical learning, creativity, and spirituality, all enactments share essential commonalities. Three interrelated themes characterize holistic curriculum: the need to cherish and nourish children’s natural goodness; creation of an integrated, thematic, and well-rounded curriculum to create individuals’ full and balanced development; and encouragement of connection to communities and the natural world to instill a desire for nonviolence and peace.

Descriptions of holistic curriculum emphasize love and respect for children and their developmental processes. As follows, holistic educators trust learners’ interests, ideas, emotions, and experiences to be principal influences on curriculum. Child development itself is seen as the process of unfolding—to reveal the inner nature of each child and to encourage children’s natural curiosity, passion for

learning, and sense of wonder and spirituality. In delineating the role of teachers, emphasis is on nurturance rather than on control and on guidance rather than on anarchy.

A goal of holistic educators is to create a balanced curriculum that fosters integration of individuals’ personalities with respect for seemingly contrasting elements of human nature such as the feminine and masculine, intellectual and emotional, or physical and spiritual. In particular, holistic curriculum centers on physical development through kinesthetic learning, movement, and rhythm; it also centers on creativity and expanded consciousness through storytelling, meditation, and visualization activities. So, too, holistic educators believe that well-rounded development emphasizes awakening spirituality by enhancing intuition, metaphoric thought, and appreciation of the mysteries of existence.

Finally, holistic curriculum focuses on helping learners to feel reverence and wonder for life and nature as well as to experience and appreciate their connections to each other in the classroom, community, and global community. Moreover, this curricular orientation’s ecological perspective fosters teaching about the dynamic and spiritual interrelation between humans and the natural world. As part of holistic curriculum, for example, children may participate in service learning, sustainable school projects, international school partnerships, activities to visualize the meaning and feeling of peace, studies of spirituality within world religions, and projects to learn about how individuals and nations resolve conflicts peacefully. For the holistic curriculum, educators create ongoing experiences to help children to feel and understand caring, connectedness, and mutuality with the aim of appreciating democracy and equality through engagement in nonauthoritarian, equal relationships.

## HOME INDEPENDENT STUDY PROGRAMS

---

Home independent study programs take many forms, but they generally refer to curricula and assessments that have been prepared for self-guided study outside the traditional school environment. The primary reasons a family would choose a home independent study program are as a supplement to a traditional education program, as a support for a homebound student, or as part of a homeschool curriculum. Home independent study programs are different from homeschooling in that a homeschool curriculum may include an independent study program, but also refers to the full range of instructor-guided and experiential learning that happens outside of a traditional school setting.

As technology changes, the delivery systems for home study programs have evolved, but even as Web-based programs grow in popularity, there are still many independent study options that are based on earlier correspondence school models. The majority of research on home study in the field of curriculum studies has been concerned with tracking the quality of home study programs compared to traditional schooling. New scholarship in curriculum studies has also emerged that analyzes the innovation and effectiveness of technologies that home independent study programs have introduced.

The most common supplement to traditional schooling comes in the form of dual credit independent study programs offered by colleges. Through dual credit programs, colleges offer coursework that students can use to fulfill both high school and college credit. Dual credit traditionally is offered in the high school or college classroom, but in home-based, independent study,

dual credit courses are a growing phenomenon. Colleges have long been involved in offering high school independent coursework in the Midwest where the distance between urban centers made distance education a more attractive option. The University of Nebraska, for example, has been running some form of college-prep independent study program since 1929.

Currently, home study programs can be found covering the whole range of standard curricular offerings. Both public and private programs are available, and many work directly with accreditation agencies and state school systems to ensure that credits will be transferable to a traditional school environment. Virtual schools have also been founded as charter schools in several states, delivering their curriculum through a blend of online faculty-facilitated instruction and independent learning. Initially, virtual school programs were designed exclusively for high school students, but now Web-based learning programs can be found that cover the full spectrum of K–12 education. The Pennsylvania Virtual Charter School, for example, is a K–12 cyber school that uses a blend of synchronous and asynchronous delivery methods. Public charters that offer virtual or independent learning programs are compliant with the same state assessment measures as other public schools.

Private, for-profit home study programs are not compelled to align their curriculum with state assessment standards. However, those privately run virtual schools that offer a full academic curriculum often seek accreditation and must register with the state as a private school in accordance with the same laws that govern the running of brick-and-mortar private schools. Comprehensive private virtual schools are relatively rare though, and it is far more common to find private education companies packaging specific independent study programs rather than full school options. Often, private independent study programs are designed as supplemental curriculum for a homeschool program. However, private home study programs, like their public counterparts, run the full gamut of curricular offerings and grade levels.

A prominent feature of the private independent study market is a curricular focus on fundamentalist Christian-based curriculum. Roughly a third of homeschooling parents cite a preference for control over the religious and moral education of their

children as the top reason for choosing to provide a home-based education. Curriculum areas that are often at the center of religious-based controversy in the traditional school setting are widely available for home study. For example, there are a wide range of private companies that offer home independent study materials that cover biology from a creationist or intelligent design perspective. Private curricular supplements to homeschool education are not regulated directly. However, each state has the right to regulate homeschool efforts either through curricular mandates or assessment programs.

## HOMESCHOOLING

---

Homeschooling is the practice of providing education to youth outside of publicly and privately funded educational institutions. Practiced by a minority of Americans, homeschooling was once the traditional method for educating youth before the national initiative to establish tax-supported public schools began in the 1820s. Compulsory attendance laws in the 19th and 20th centuries rendered homeschooling illegal in most states until the 1980s. During the last three decades, various groups have worked to expand parents' rights to homeschool their children and by 1993,

ensure its legal status nationwide. Homeschooling inspires citizens' curiosity and skepticism for many reasons: Public schooling is such conventional practice that its dismissal seems suspect; governmental oversight of homeschooling varies drastically from state to state; and parents are generally neither trained nor credentialed educators. However, these concerns matter little to homeschoolers critical of overcrowded schools, overworked teachers, or secular curriculum. Historically, groups instrumental to the homeschooling movement have included religious fundamentalists seeking religious-based education and members of the counterculture seeking liberating and flexible curriculum. In recent years, others have advocated homeschooling to serve children with diverse abilities, to provide individualized attention, and to ensure safe learning conditions. Indeed, advocates suggest the choice, innovation, and individualized attention homeschooling offers exemplify the true ideals of educational freedom foundational to democratic education. The movement's varied curriculum reflects these diverse philosophies.

### Growth of Homeschooling

Widespread dissatisfaction with the quality of public schooling has fueled the growth of homeschooling since the 1960s. Two groups with strikingly different ideologies and curricular visions have been instrumental to its growth: members of the counterculture and religious fundamentalists. Although these categories do not represent the full diversity of homeschoolers' philosophies, they provide a general guide for understanding significant arguments shaping the movement. The first group of homeschooling advocates was critical of the bureaucratic and authoritarian character of public schools. John Holt, a humanist educator, argued that such environments damaged children's natural love of learning. Holt drew from the spirit of educational and social reform prominent in the 1960s and 1970s to advocate for more humane ways of educating children. He envisioned an unschooling approach with unstructured curriculum in which children followed their own interests and learned at their own pace. Some scholars today refer to this group of homeschoolers as pedagogues.

The second group of homeschooling advocates was similarly critical of public schools' educational methods and of their secular content. Pioneer Christian homeschoolers Raymond and Dorothy Moore considered young children too fragile to attend school. They recommended delaying children's entry into formal schools until they were physically and developmentally ready (between ages 8 and 12). The Moores believed parents were children's natural authorities and thus superior teachers to any the public schools could provide. In this view, parents' instinctual knowledge of their own children and the intimate and protective character of the family unit provide ideal learning conditions. Scholars sometimes refer to homeschoolers in this group as ideologues today.

Many homeschoolers share a common conviction that the homogenizing curriculum of contemporary public schools simply cannot accommodate each child's profound individuality and unique gifts. Whereas public school teachers must negotiate 20 or 30 students at a time, home educators teach only a few children in a comforting family environment. To homeschoolers, such individual attention is a foundational strength of their unconventional educational choice. Some prefer the term *home education* to differentiate their learning activities from conventional bureaucratic schooling.

### Homeschool Curriculum

Homeschoolers use varied approaches to tailor curriculum to children's needs, abilities, and learning styles. Those who value Holt's educational philosophies (the unschooling approach) believe rigid timetables can stifle children's natural inclinations and favor creative and experiential learning that children generally lead and direct. In this view, learning looks very much like living. The living curriculum of a typical school day may include a trip to the library, imaginative play, reading aloud, gardening, playing board games with siblings, researching materials used in an art or construction project, caring for the family pet, or learning measurements through cooking. Under a parent's watchful eye, any activity can become a vehicle for learning math, grammar, or science. In a related approach Charlotte Mason developed, parents might provide 1 hour a day of structured

academic instruction and then spend the remainder of the day sketching in nature, learning poetry, and most importantly, fostering children's natural love of learning. Parents who support child-directed methods typically perceive television and video games as potentially corrosive to children's development and encourage more interactive and imaginative pursuits. In this view, inclination is a powerful teacher, and students may choose to read one book all day if they want to.

Other homeschooling curriculum is parent-directed and structured. Parents serve as role models for and protectors of their children and orient their children's curriculum to their family's values. Such priorities may include religious beliefs, cultural or family heritage, or community activism. Rather than allowing children to follow random inclinations or mingle with worrisome peers who might lead them astray, parents tend to adapt the discipline and structure of public school classrooms to their family setting. A typical day may include Bible reading, chores, and guided textbook lessons. The Moore's contemporary curriculum suggests integrating study with community service and manual work. Many who use parent-centered approaches designate a particular time for formal instruction and favor traditional curriculum such as distance learning courses, textbooks, and scripted computer programs offered by Christian or secular providers. Some supplement vendor curriculum with writing lessons, athletics, atlases, piano lessons, and a variety of activities to learn social skills. In this approach, parental rather than child or governmental authority provides the foundation for learning.

The resources available for assisting parents in their educational roles are a vital aspect of homeschooling curriculum. Homeschooling families in the United States are overwhelmingly two-parent families with one parent, usually the mother, remaining out of the labor force to provide home education. The significant responsibility of serving as both parent and educator for young children necessitates support. Many families join national homeschooling organizations to help balance parental responsibilities with writing curriculum, developing lesson plans, and identifying materials. Resources for home educators abound, including teaching guides, sample lesson plans, grading rubrics, newsletters, seminars, college preparatory

guides, Internet chat sites, teacher-assistance hotlines, log sheets for recording classroom hours, scripted responses homeschoolers can deliver to skeptics, and practical tips for teaching children of differing ages and abilities. Also available are guides for serving teens, special needs students, and gifted students.

Home educators utilize varied methods to accomplish their learning objectives: the Internet, scripted computer software programs, music, religious texts, documentaries, support groups, experiential learning, extracurricular activities, and library books. Computer approaches are common tools parents use to individualize learning. Children use online resources to complete lessons at their own pace. The Trivium approach teaches the fundamental principles of any subject of study using a curriculum of three subjects: grammar, logic, and rhetoric. The Unit Study approach involves comprehensive study of one particular topic for weeks or months at a time. Curriculum might include art, drama, cooking, and museum trips centered on that particular theme. Other families use traditional correspondence programs with structured curriculum, step-by-step instructions, and instruments to test knowledge. Some correspondence programs document student progress. Report cards, transcripts, and diplomas provide tangible evidence of progress for state requirements or college entrance.

Christian publishing houses offer a wealth of curricular options that seamlessly integrate Biblical and academic lessons for children of toddler to teen age. Health lessons may direct students how to keep their bodies pure and free of contaminating substances. Science curriculum may describe creationism and dismiss evolutionary theory. Math lessons may include a tithing budget. Some texts provide structured lessons in character education. Others orient academic subjects around religious themes to link diverse bits of information into a coherent structure.

### Criticisms of Homeschooling

Despite the academic success and popularity of many homeschooling efforts, strident critiques of homeschooling persist. Indeed, some see homeschoolers' rejection of public schools as part of a larger trend toward privatization and as a selfish

affront to democratic principles in which public interests are sacrificed for individual interests. In this view, "my child's education" is considered a more important entity than "our children's education." Another criticism is that homeschooling is regulated too erratically from state to state to ensure that children receive a rigorous education or learn the skills necessary for effective citizenship. Although some states require home educators to hold teaching credentials, use state-approved curriculum, or follow compulsory attendance laws, other states do not require any evidence that children are meeting minimal educational standards, or in fact, attending school at all. In this view, limited accountability required of homeschoolers runs counter to the government's investment in creating an educated citizenry and responsibility to provide all children equal educational opportunities.

Another criticism emerges from the assumption that any parent can step into a teaching role effectively. This do-it-yourself approach distresses educators who have spent years training to teach and developing expertise in their respective fields. Indeed, teaching geometry, history, literature, and the periodic elements might challenge any individual. Others suggest that homeschooling does not provide sufficient opportunities for diverse social interaction or for the arts. What a parent envisions as ideal curriculum may in fact limit their children to narrow perspectives and experiences that do not reflect the wider social world. Although this may be a goal of some homeschoolers, critics argue that children benefit from exposure to diverse ideas that multiple teachers and peer interaction provide in public schools. Some fear that in the guise of protecting children and celebrating educational choice, such education may limit children's experiences and erode support for public education.

## HOMWORK

---

Homework is defined as the tasks assigned by school teachers to be carried out by the students during nonschool hours. Homework is usually given to enhance learning by practicing or enforcing skills. Some homework assignments aim to prepare students for future lessons. Occasionally, homework is used as a punishment of students. However, the use of homework as a curricular and instructional tool is not without debate. The homework debate has a direct impact on the curriculum because teachers and curriculum specialists have to determine the role homework plays in students' learning. As a result, they have to consider the nature and amount of homework they can include in the curriculum.

### The Homework Debate

Many parents today complain that teachers assign too much homework to their children. Such practice, some argue, results in high stress for students and their parents, infringement on the family social time, sleep deprivation, and early burnout for students. Some attribute the increased homework load to the pressure for schools to improve their students' scores under No Child Left Behind Act mandates.

Proponents of homework argue that most studies prove positive effects for homework. Educators argue that when homework was graded and feedback was provided, homework has positive effects on students' learning. Harris Cooper maintained that homework has positive impact on students' learning, but the impact varies for different grade levels. He reasoned that homework should be

decided based on the students' developmental needs and home circumstances.

Cooper, James Lindsay, Barbara Nye, and Scott Greathouse conducted an extensive series of studies on the effects of homework. The results of their studies can be summarized as follows: There were no significant effects for homework on grades or test scores. They found negative effects for the amount of homework on test scores for young students and no significant effects for older students.

Opponents of homework argue that teachers are assigning more homework to deflect criticism for inability of schools to prepare their graduates to compete in a global society. Teachers, on the other hand, argue that U.S. students spend less time on homework compared to their counterparts in Europe and Asia.

Some educators argue that excessive homework was one of the contributing factors to high school dropout. They argued that teachers cannot ensure that students are doing their homework. They argued that high school students are challenged to participate in a variety of activities to compile an impressive college application, and homework adds an undue stress on these students. Some schools around the country, concerned about students' burnout, established guidelines to limit the time students spend on homework each night.

### Teachers

Homework can elevate the Mathew's effect: Parents from low socioeconomic and educational background can provide little support to their children at home, while parents from high socioeconomic and educational background are more able to provide support to their children at home. This practice can directly contribute to increasing the gap between the poor and rich children. Therefore, it has been suggested that teachers recognize the existence and effects of the Mathew's effect.

It has also been suggested that teachers need to move away from the habit of assigning homework because it is expected of them, and they need to rethink homework assignments in terms of objectives and quality. Alfie Kohn contended that if teachers would consider these issues, the quality of students' learning will improve. He recommended that teachers design homework assignments that

are suitable for the home environment. These assignments should be tasks that students cannot perform at school, involve the parents, and can be considered family activities. Teachers should encourage students to read leisurely at home without making demands on them to read certain books or prove that they read them to help motivate students to read. In addition, students should be given a choice in their homework assignment.

### Curriculum Design

Many curriculum scholars believe that the role of homework in students' learning should be part of curriculum design. To many, it is an issue that should be researched and debated in the colleges of education to better train teachers to construct, grade, and give feedback to students on their homework for it to be effective. By developing homework assignments that are varied in nature, curriculum specialists can address students' different learning styles and home environments.

## HORACE'S COMPROMISE

---

A highpoint in U.S. concern over education, the 1980s was a decade awash in reports lamenting the fundamental unpreparedness of the schools for new global economic challenges. 1984 saw the publication of a rather different, if equally

fundamental, rethinking of schooling: Theodore (Ted) Sizer's *Horace's Compromise: The Dilemma of the American High School*. The first fruit of the 5-year, collaborative Study of High Schools, *Horace's Compromise* signaled a new era in curriculum studies and school reform. Sizer vividly illustrated how the cart of school structure had gotten in front of the horse of curriculum and pedagogy, reminding us to begin with the essential questions: What needs to be learned, and how can we support teachers and students to do this work?

Sizer introduces his critique of the high school through composite portraits of teachers and students. Horace Smith is a 28-year veteran English teacher whose inescapable compromise points to the inadequacies of high schools. Daily, Horace juggles five classes, 120 students, responsibilities as faculty advisor for the drama department, and a second job to make ends meet. Horace, like the U.S. high school, is stretched too thin, and this leads to compromises in the most crucial areas of his teaching. He has too many students to give detailed feedback on writing assignments: He is lucky if he can devote 5 minutes per paper. He has no time for thorough class preparation, let alone deep study: He must settle for a meager 10 minutes per lesson.

As Sizer shows, high school teachers find themselves in the paradoxical position of being too overburdened and underpaid to realize the fundamental aims of teaching and learning while simultaneously being held responsible for the problems of the system that weakens their agency.

In his portraits of students, Sizer captures both the vulnerability and the potency of adolescence. We meet Will, a preppy and somewhat insecure senior, and Louella, a 15-year-old former prostitute and new student at an inner-city, Catholic high school. We see students like them shuffled from class to class—bells ringing every 50 minutes—passive recipients of an incoherent curriculum. Sizer reminds us that after school these same young people will come alive in bustling worlds of social interaction and self-driven activity. Sizer wants to see this initiative present in the classroom.

Such portraits bring the problems of the U.S. educational system down to a human scale. And this is no mere writerly device. Returning to the human dimensions of teaching and learning is the heart of Sizer's plea for curricular reform. Public

education has become a massive bureaucracy, which loses sight of the essentials of teaching and learning and the people who drive the process.

Sizer's return to essentials begins with a look at the classic instructional triangle of student, teacher, and subject matter. He emphasizes the active role of the student in learning, denying that a teacher can give an education. The teacher is thus recast from information dispenser to coach. Because student motivation is so crucial to the educational process, Sizer boldly asserts that compulsory education should cease when students have exhibited proficiency in literacy, numeracy, and civic understanding. Once these essential skills have been mastered, high school should be viewed as an opportunity, not an obligation.

Sizer's overarching curricular principal is less is more: less content coverage and more meaningful instruction in core areas. Following Mortimer Adler, Sizer calls for a pedagogy of questioning to develop student's powers of understanding and coaching to cultivate thinking and communication skills. Didactic methods geared toward knowledge acquisition would still have their place, but Sizer's progressive model prioritizes how students think over what they think.

In Sizer's vision, education is people driven, not system driven and schools refocus on the essentials: giving teachers the resources to devote themselves fully to the craft of teaching and helping students become confident and purposeful learners. Sizer founded the Coalition of Essential Schools to put his ideas into practice. *Horace's Compromise* was followed by two sequels: *Horace's School* and *Horace's Hope*.

## HOW TO MAKE A CURRICULUM

---

John Franklin Bobbitt's *How to Make a Curriculum*, published in 1924, was a targeted sequel to Bobbitt's groundbreaking and highly popular book *The Curriculum*, which appeared in 1918. *How to Make a Curriculum* focuses on Bobbitt's detailed process of curriculum making, whereas *The Curriculum* addresses the much larger subject of curriculum itself. In *The Curriculum*, Bobbitt was making his initial case for his philosophy of curriculum. In *How to Make a Curriculum*, on the other hand, Bobbitt assumes that his view had taken root and then proceeds to explain how to make curriculum in detail.

Bobbitt wrote *How to Make a Curriculum* to provide specific guidance to schools and school districts that were facing the problem of needing to revise their curriculum during the mid to late 1920s. The United States was changing rapidly due to pressures such as industrialization and immigration, and many people began to believe that the U.S. public school curriculum had become outdated. Bobbitt provided school administrators and teachers with a process they could use to revise their curriculum to match the new age. In this respect, Bobbitt intended for the book to be deeply practical in the sense that he wanted it to provide specific guidance, rooted in the new social sciences, about how school practitioners could develop their curriculum most effectively.

Making sense of *How to Make a Curriculum* begins with recognizing how Bobbitt viewed the purpose of education. To Bobbitt, education exists to prepare young people for the various activities they will perform as adults. Life is about activities, and schools should prepare young people to perform them. At first glance, this purpose seems narrow, but to Bobbitt it is quite expansive. Bobbitt's goal was to make society more efficient by training people for the roles they will play as adults, be they construction workers or lawyers or teachers. Bobbitt explains the process of activity analysis, which he created to show public school workers what they should do to revise their curriculum. He

explains how practitioners should analyze adult activities and then use the results of this analysis to establish educational objectives.

Bobbitt acknowledges that any curriculum revision project must begin by looking at the adult activities in a particular community, but he also conducted research to capture adult activities across the country. This research led him to break down all human activities into 10 categories: (1) social intercommunication, (2) physical efficiency, (3) efficient citizenship, (4) social relationships, (5) leisure, (6) mental efficiency, (7) religion, (8) parental responsibilities, (9) unspecialized practical activities (such as taking care of the house), and (10) occupational activities. Bobbitt argues that all human activities can be classified within these 10 categories. He then breaks down each of these areas into highly specific skills that all students should develop, a list that came to a total of 821. Bobbitt defined productive citizens as people who were effective at performing all 821 skills, which by definition could be observed and measured.

In later chapters, Bobbitt takes his 821 objectives and categorizes them based on the various subject matter fields. He shows, for example, how the objectives that he lists under effective citizenship can be fostered in social studies classes and how the goals included in his leisure category should be developed in courses on literature. All of the subject matter fields must be tied to the original 821 objectives that Bobbitt asserts are the foundation for schooling.

*How to Make a Curriculum* met the need that it was meant to serve in the 1920s. Public school practitioners needed to revise their curriculum, and Bobbitt provided them with a book that told them how to do it. The influence of the book should be recognized as both positive and negative. Bobbitt understood the challenges that school administrators faced, and he provided them with a method they could use to change with the times. He also makes the point that curriculum should serve societies in a way that is broader than personal culture or the particular interests of students. At the same time, however, Bobbitt's view of curriculum making has been criticized for the way in which it tracks students into narrow societal roles, as opposed to broadening their opportunities. In addition, Bobbitt's view of human nature, which he does not discuss at length, is at odds with the

U.S. view of equality. For example, Bobbitt maintained that knowledge of a second language was appropriate for those with great ability and not necessary for the general public. He also believed a broad vision of humanity was possible for only those students of high intelligence. In making arguments such as these, Bobbitt helped to redefine "democratic curriculum" to mean the opposite of giving all students the same high-quality curriculum. Instead, he redefined democratic curriculum to mean giving each student what he or she needs to fill his or her economic role in society. Debates surrounding the merits of this vision remain highly contested today.

## HUMAN ECOLOGY CURRICULUM

---

Scholars in the field of curriculum studies investigate and support a variety of interdisciplinary, multidisciplinary, and transdisciplinary approaches to education. Human ecology is an interdisciplinary field of study and research that encompasses a variety of disciplines from the ecological sciences to the arts, humanities, and social sciences. The term can refer to virtually all aspects of human experience and the interrelationships within and between human communities and natural and human-constructed environments. The human ecology curriculum covers a broad range of issues including the human impact on the environment, how environmental conditions shape the human experience, environmental problems and some of their solutions, and environmental art and design. Human ecology programs and courses of study are mostly housed in institutions of higher education at the undergraduate, master's, and doctoral levels, and studies lead to certificates,

options, specializations, or degrees. In K–12 education, ideas from human ecology are sometimes embedded in family and consumer science courses, but there is no concerted, nationwide effort in the United States to institute programs in human ecology in public schools.

In the United States, the academic field of human ecology is indebted to a number of early scholars. Harlan Barrows (1877–1960) was a historical geographer and chair of the department of geography at the University of Chicago from 1919 to 1942. He was influenced by Frederick Jackson Turner (1861–1932), a historian who explored the connections between culture, history, and the environment, especially around issues of westward expansion, and Ellen Churchill Semple (1863–1932), an early proponent of the idea that geography influences, even to some extent determines human society. In the early 1920s, Barrows shifted his focus from the effort to scientifically determine geographic influences on human society to a broader emphasis on human ecology, which laid the foundations for the current interdisciplinary field. His presidential address to the Association of American Geographers in 1922, “Geography as Human Ecology,” remains one of the most frequently cited historical works in the field. Following Barrows, R. D. McKenzie used the term in a paper titled “The Ecological Approach to the Study of the Human Community,” in a 1925 book. Although human ecology in its inception was considered a subdiscipline of sociology, it is now also associated with anthropology, psychology, political science, or the ecological sciences, among other disciplines, depending on the school of thought, institution, or country.

Human ecology as a field of study also has roots in home economics or domestic science, itself an interdisciplinary area of study that emerged in tandem with the Cooperative Extension Service, administered by the land grant institutions. The institutional history of the field can be illustrated by the development and evolution of a representative program at the University of Wisconsin-Madison. The department of home economics began at Madison in 1903; became the School of Home Economics in 1951, within the College of Agricultural and Life Sciences; and in 1973, became an independent unit first named the School of Home Economics, then the School of Family

Resources and Consumer Sciences, and finally, the School of Human Ecology. These shifts represent increasing awareness of the interconnectedness of human activity and the environment as well as the global impact of local, domestic decision making and practices.

Contemporary academic journals dedicated to the topic of human ecology include the *Human Ecology Review*, the semiannual journal of the Society for Human Ecology (SHE), which began in 1993, and *Human Ecology: An Interdisciplinary Journal*, which began publication in 1972. Published studies in human ecology are international and historical in scope, and research in the field encompasses a vast array of topics, including but not limited to population issues, hunting, land use, technology, animal rights, environmental racism, the impact of toxic chemicals, civic participation, health and health systems, climate change, environmental activism, gardens, urban environments, architecture, fire ecology, and a host of theoretical and methodological issues.

Related to human ecology, the field of social ecology has a more explicit focus on the social and political dimensions of human interactions. The School of Social Ecology at the University of California, Irvine, for example, is an interdisciplinary program that focuses on research and instruction in the social, behavioral, legal, environmental, and health sciences. A more explicitly radical-political approach to social ecology was developed by Murray Bookchin, a left-libertarian social theorist (1921–2006) who wrote more than 2 dozen books encompassing history, politics, ecology, philosophy, urban planning, and economics in which the detailed principles and practices of social ecology as a social movement are worked out. Bookchin believed that the roots of the multifaceted ecological crisis lie in the hierarchical organization of power under the economic system of capitalism. He asserts that ecological problems cannot be solved without attention to social relations and proposes an egalitarian, radically democratic, decentralized society based on communitarian values.

The curricula of human ecology and social ecology, despite their diverse theories, content, and emphases, share a number of characteristics. First, there is a recognition that the complex problems of modern society, whether defined as environmental problems, political problems, or social problems,

are interrelated and cannot be compartmentalized. Therefore, they must be studied in an interdisciplinary, holistic way. Studies in these areas lend themselves to problem-based, individualized, student-designed projects—progressive approaches to student learning that have been developed, studied, and explicated in the historical and contemporary field of curriculum scholarship. In many programs, students spend substantial time in the field working as interns with organizations or carrying out ethnographic studies. Human ecology curriculum is as complex as life itself, demanding of the students that they cross intellectual boundaries, bring ideas from widely divergent fields and multiple perspectives together, and work to generate fresh combinations of concepts and new knowledge that is capable of solving the many pressing social and environmental problems in the world today.

## HUMANIST TRADITION

---

The humanist tradition within curriculum studies emphasizes literature, foreign languages, reason, and the complete development of human excellence, or virtue. In the United States, a humanistic approach to curriculum dominated K–12 schooling, as well as higher education, well into the late 20th century. Humanities subjects such as Greek, Latin, philosophy, and theology served as the

foundation for U.S. curriculum until the rise of the physical sciences and later the social sciences in the 1880s and 1890s.

Humanists raise eternal questions that have been discussed since the beginning of time: What is human nature? What is reason? What should I do? What is the purpose of Man? And why are we here? For answers to these questions, humanist scholars look to models of scholarship that have proven their worth over time, whether they be works of literature, philosophy, or theology. Humanists also search for defining principles and methods that hold together all fields of human inquiry. As F. C. S. Schiller (1907) puts it, humanists search for a method that is universally applicable to ethics, aesthetics, metaphysics, and theology as well as to a theory of knowledge. To humanists, older texts are almost always superior to new texts primarily because they have stood the test of time and as a result, remain relevant to each passing generation. Humanists stress that a good curriculum, one fit for human beings, must introduce students to classic works from philosophers, poets, and literary scholars such as Homer, Aristophanes, Plato, Aristotle, Saint Augustine, Virgil, Jean-Jacques Rousseau, and C. S. Lewis. Because classic texts were written in various languages, humanists emphasize that, if these texts are to be understood, students should read them in their original languages. As a result, the humanist tradition encourages the study of numerous foreign languages, especially Greek, Latin, and Hebrew. In addition, humanists believe that the rigor required to learn a foreign language teaches students discipline, opens their minds to new and different cultures, and trains their God-given ability to reason. Humanist scholars, for example, Harvard University literature professor Irving Babbitt and British poet Matthew Arnold, promote virtues such as excellence and honor while often de-emphasizing equality and democracy.

Until the late 20th century, the justification for humanities subjects within the curriculum could be found in the psychological theory of formal discipline. Adherents to formal discipline believed that studying humanistic subjects like philosophy and Greek trained students' ability to reason. They also believed that this ability to reason transferred automatically to all areas of life. For example, humanists believed that the power of reason that students

developed while conjugating Latin verbs automatically helped them when they were running a business or planning a vacation later in life. The new empirical science of psychology in the early 20th century, however, claimed to undercut the theory of formal discipline. These studies, produced by Edward L. Thorndike and Robert S. Woodworth, led to the dismantling of humanities-based curriculum in K–12 schools and in universities.

Another major blow to the humanist tradition within curriculum studies came with the secularization of private universities. During the early to mid-19th century, the religious mission of many private universities required that all students read and discuss texts that were central to the Christian faith. Once these universities secularized, few if any central texts were required reading of all students. As a result, the humanist tradition began to take a backseat to the physical sciences, the social sciences, and other professional fields such as business and engineering. The humanist tradition has not yet recovered from these two major developments more than a century ago.

## HYBRIDITY

---

Biologically, hybridity refers to the crossing of genes, but this term is a metaphorical trope describing the postcolonial position by referring to the merging of two socially, culturally, economically, or politically separate spheres or the blending of elements, characteristics, or traits from two different cultures. In relation to education, then, hybridity

has come to be seen as a possibility for deconstructing dominant curricula and pedagogy and moving toward a socially just system of education.

Brian Stross, a theorizer of hybridity, notes that humans are categorizing animals. People tend to classify everything into distinct boxes with nonporous borders. What happens with this type of classifying is that categories are established as pure and unchangeable. In addition, classifications are hierarchically arranged, with some categories established as dominant and others as inferior. In this way, categories tend to be created in terms of binaries such as good–bad, white–black, male–female, heterosexual–homosexual, and so on. In each of these categories, one is established as more powerful, more pure than its counterpart.

Purity, however, is a falsity, and the development of categories is not an innate desire in humans, but one that is socially constructed. Nonetheless, the notion of purity can be established by the dominant group because of its power. Often the characteristics of the dominant group are normalized or naturalized and thus come to be accepted as universal. By continually categorizing and creating borders, the dominant group establishes a façade that appears pure, impenetrable, and static. These borders, however, are not impenetrable, and identity in these categories is not static. The dominant group constantly works to police borders to ensure that categories do not mix. This control can be seen to occur in schools, for example, with structures such as tracking and sorting where students from nondominant groups are marginalized, pushed into lower tracks, or sorted for jobs in a lower socioeconomic sector. In terms of curriculum, too, dominant cultures and ways of being have been presented as part of the accepted curriculum while subordinated groups have been ignored in textbooks and classroom content.

The hybrid, though, is a threat to the dominant group. Culturally speaking, hybridity refers to what happens with colonization or when dominant groups forced nondominant peoples to assimilate to dominant cultures. This metaphor applies to modern society as well. The hybrid, then, is someone who represents a mix of cultures and is expected to assimilate to dominant culture at the same time that he or she is never fully accepted into this culture. The hybrid is in a liminal state,

then, and might not feel a sense of belonging to either culture. As a result, hybridity can result in feelings of double consciousness, as first described by W. E. B. Du Bois.

At the same time, however, hybridity opens up the possibility for change. Gloria Anzaldúa and Homi K. Bhabha argue that the creation of third spaces or borderlands where individuals and groups examine hybridity can help people understand how dominant society works to maintain power and can allow a space for the deconstruction of dominant ideologies. It is in this space in between these constructed categories and borders that people can look at historical, social, and cultural constructions of identity. It is also the place where people can begin to realize identity as something porous and unfixed rather than as static, essential, or pure. Also, it is in this space that people can deconstruct dominant society and understand that it is not monolithic. Hybridity can result in the creation of an in-between space to breakdown hierarchical dichotomies.

Scholars such as Henry A. Giroux have argued that the development of third spaces and borderlands is something that needs to happen in schools, which are a microcosm of the larger society. Giroux, for instance, argues for a pedagogy of difference through which classrooms can examine identity and the creation and maintenance of dominant ways of being. Many postcolonialists and feminists have argued that classrooms should provide space for the examination of dominant and nondominant-hybrid identities and space for previously silenced hybrid voices to emerge.

One problem with hybridity, however, is that it fails to move beyond dichotomies in its very theoretical underpinning. Identities are not necessarily comprised of one or two cultures, but are comprised from multiple and varied elements. In addition,

some have argued that hybridity tends to be too celebratory. As Anzaldúa reminds us, though, hybridity can be a painful position, and the journey through the borderlands to conscientization is often tense and difficult. In addition, this is a journey that cannot be made by hybrids alone. After all, deconstructing dominant ideologies is a huge task, an impossible burden for the hybrid. Those from the dominant group must participate in these discussions as well and need to examine their own identities at the same time. Moreover, scholars and practitioners have to be careful that hybridity does not reinforce power relations and have to examine resistance to hybridization.

## IDENTITY POLITICS

---

Identity politics within curriculum studies finds at its root the link between one's individual history and cultural experiences and the course of study, or curriculum, at hand. In short, identity politics in curriculum studies brings together oneself with the curriculum. Scholars of identity politics ask questions about whose identity is being taught in the curriculum, whose is not, and why?

Emerging as a significant field of inquiry and in response to the political tensions and historical events of the 1960s, the field of identity politics within curriculum studies was birthed during an era when the majority population, and its traditional dominance over politics, started to be questioned, especially in terms of civil rights. In the 1960s, in short, curriculum studies scholars began to draw attention to the idea that civil rights was a political issue influenced by one's identity, and as it turned out, they reasoned, those who held political power made curriculum decisions. As a result, whoever held political power also held power over the curriculum. Those in political power used their power—knowingly or unknowingly—to have their identity represented in the curriculum. And in reverse, those who did not hold political power—minority and cultural groups of all kinds—held no power to influence the curriculum. Their identities were not represented in the curriculum.

Yet curriculum studies scholars continued to note, despite any minority or cultural group's absence from the curriculum, a message about

their identity, and their power was still being communicated. The message was simple: What matters is represented in the curriculum, and what does not matter is not represented in the curriculum. Since their identities were represented, those who held political power supposedly matter. Since their identities were not represented, those who did not hold political power supposedly did not matter, or so the message communicated. Minority groups, in essence, found themselves underrepresented in the curriculum and their voices (or identities) silenced.

Over the years, as scholars of identity politics began to emerge from all types of minority groups, the political implications of these curriculum messages were exposed. Scholars pointed out that if the field of curriculum studies allowed any one, dominant majority to control (or have power over) the curriculum, then students would receive—because of what the curriculum taught them—only that majority's view of what mattered. Traditionally, the dominant group to have political power over the curriculum, and have their identity represented, was a White, male, heterosexual view.

Under this premise, curriculum studies scholars and civil rights activists began to question the legitimacy of who held the power to make curriculum decisions. They asked the following questions: Who holds the power? Who does not hold the power? Who is represented, and who is not? What are the political implications of having or not having representation in the curriculum? What messages are being sent as a result of having or not having political power in the curriculum? In answering these questions, identity politics

scholars have found that the curriculum should represent all people, not just the majority. Students would benefit from hearing from a diversity of identities and their political leanings, they argued. So scholars of curriculum studies set out to create a different future for students, a future that would embolden educators to make curriculum decisions that attempted to place value on all people and on all voices.

Over the years, curriculum studies then focused on research that considered diverse identity groups. This goal of this research was to expose each identity group's political view and how that view was or was not reflected in the curriculum being taught. If that identity group's political view was not represented in the curriculum, suggestions for how to include that group were offered.

Since the 1960s, then, the social mainstream's reliance on a White, male, heterosexual point of view changed. Curriculum decisions were made diverse identities and diverse political beliefs. Students started to learn about a diverse range of individual identities and why each mattered. Students also started to become more aware of how different identity groups had their own political viewpoints, which were related to their histories and cultural backgrounds.

The underlying goal of identity politics in curriculum studies is to question how socially just or unjust the curriculum may be. And rather than accept a dominant group's hold on the curriculum, scholars of identity politics feel that the curriculum should be questioned and should be socially dynamic and multidimensional, representing as many different identities and their political beliefs as possible. When the curriculum is able to represent various identities, it will then have a more positive, all-inclusive message that benefits all students.

## *IDEOLOGY AND CURRICULUM*

---

Michael Apple's *Ideology and Curriculum* is a foundational text in the new sociology of education and in curriculum studies more broadly. In particular, Apple's *Ideology and Curriculum* interrogates the connections between economic and social reproduction and everyday school life and curricular knowledge. Although considering a range of oppressions, *Ideology and Curriculum* focuses largely on the reproduction of economic inequality. In this regard, Apple's book was one of the earliest and most prominent examples of neo-Marxist curriculum theory in the United States, largely setting the stage for a generation of scholars interrogating the links between social reproduction and the curriculum.

Perhaps the most lasting and enduring contribution of *Ideology and Curriculum* has to do with the interrogation of curricular knowledge. As Apple made clear, curricular knowledge does not stand outside of existing power structures and relationships. That such knowledge typically appears neutral or disinterested only underscores its particular force and power. Drawing on the work of Antonio Gramsci and Raymond Williams, Apple highlights the ways in which ideology, hegemony, and selective tradition work to produce certain forms of legitimate knowledge in school settings. By ideology, Apple refers to the ways distinct political agendas and ideas are linked together to create broader and more cohesive explanatory mechanisms. In *Ideology and Curriculum*, Apple focused on the ideological press for new forms of standardized management and control in school life. These ideological forms saturate everyday life in schools, including through the proliferation of legitimate forms of knowledge.

Such ideologies work to maintain what Apple (drawing on Gramsci) called hegemony. As opposed to more coercive forms of social control, hegemony works to legitimate existing forms of power through

the production of common sense. In *Ideology and Curriculum*, Apple discusses the role of the curricula in maintaining existing, hegemonic social relations. For example, he discusses the ways social conflict is elided from existing school life in favor of more seamless narratives of social cohesion. Here, as well, a seemingly neutral scientific curriculum is favored over and above one that engages in social and economic conflicts, including those around social class. For Apple, structural economic inequality is naturalized, made to seem immutable—just the way things are. School knowledge is a key site where this common sense is produced.

School knowledge is also a product of what Apple calls (following Williams) selective tradition. That is to say, the school curriculum reflects only certain kinds of knowledge and not others. When one sees the curricula as selective, Apple demonstrates, one sees it as the product of invested actors, situated in particular social, cultural, and economic contexts. Knowledge does not simply fall from the sky. As Apple argues, when one sees the curricula as selective, one must explore the political implications of knowledge selection and transmission. In years to come, Apple would extend this focus on the so-called official curriculum to explore the range of ways in which the curricula work to benefit certain groups and interests and to marginalize others.

*Ideology and Curriculum* highlighted the ways school life is saturated by hegemonic forces. Although the focus was largely on the curricula, he also stressed the ways teachers, researchers, and other educative agents worked to normalize this technical approach to school life. In particular, he looked at the proliferation of particular, remedializing categories and labels and how the field of education sorts young people by and through categories and labels such as slow learners, under-achievers, and so on. These categories and labels are deployed in the service of technical rationality—used to sort young people by so-called ability to seemingly maximize the school's resources most efficiently. As Apple argues, these categories and labels work as part of a self-perpetuating cycle, perpetrating inequality in the service of seemingly neutral, clinical, or remedializing ends.

This focus on ideology, hegemony, and selective tradition would mark Apple's approach to the field of curriculum studies—one that looked to

explore the connections between the organization and selection of school knowledge and broader social structures. In many respects, Apple offered the U.S. field a more sociological approach to the curricula. Although this approach was the focus of others in the so-called new sociology of education, including Geoff Whitty and Michael Young, these scholars worked primarily out of the United Kingdom and focused largely on social class. Apple was one of the first to bring these concerns to the United States. In focusing on school knowledge as a site of hegemonic control, Apple helped set the stage for a generation of critical pedagogues in the United States—that is, he helped open up a space for educators to contest power through rearticulating everyday school knowledge and practices.

*Ideology and Curriculum* is currently in its third edition. It is part of what Apple calls a trilogy of books, including *Education and Power* and *Teachers and Texts*. Other notable books among his many include *Official Knowledge* and *Educating the "Right" Way*. A retrospective collection, *Ideology, Curriculum, and the New Sociology of Education: Revisiting the Work of Michael Apple*, edited by Lois Weis, Cameron McCarthy, and Greg Dimitriadis, was published in 2006.

## IMMIGRANT AND MINORITY STUDENTS' EXPERIENCE OF CURRICULUM

---

The world is becoming increasingly multicultural and multilingual. The United Nations Educational,

Scientific, and Cultural Organization reported that more than 6,800 languages including 114 sign languages were in use in 228 countries in 2000. Approximately 185 million people worldwide live outside their countries of birth, up from 80 million three decades ago. The foreign-born population in 2004 represented 23.6% in Australia, 18.8% in New Zealand, 18.0% in Canada, 12.8% in the United States, 12.2% in Sweden, 10.6% in the Netherlands, and 7.8% in Norway. Immigrants, migrants, and their children bring language, cultural, and ethnic diversity to countries, societies, communities, schools, and classrooms.

Immigrant and migrant students strive to learn to speak, to read, and to write in new languages while their families struggle with political suppression, cultural insecurity, and poverty. The linguistic heritage, cultural knowledge, and experience these students, other minority students of color, and their families bring to schools, however, are often ignored or overlooked. Their academic, physical, emotional, and social development challenges associated with economic insecurity or poverty are exacerbated by language barriers, displacement, alienation, exclusion, acculturation processes, and limited access to equal opportunities to learn or to live. The cultural and linguistic diversity and complexity are the curricula immigrant and minority students experience inside and outside schools. To cultivate curricula of creative diversity and harmonious plurality for immigrant and minority students and all other students to reach their highest potential emerges as one of the urgent challenges facing 21st-century curriculum workers.

### Research on Immigrant and Minority Students

Research on immigrant and minority students of color can be found in empirical research, reflective essays, and books on demographics research, immigration patterns and policies, acculturation and enculturation, voluntary and involuntary immigrants, bilingual education, multicultural literacy, and race, gender, and class issues. This work, however, contributes to a theoretical understanding of the sociopolitical and cultural context of education of immigrant and minority students of color. Although there is a wide array of literature on immigrant and minority students of color,

there is less literature focused on their school experiences. There is a need for more research examining ways in which schooling shapes cultural and ethnic identity and a sense of belonging in schools and communities; ways in which achieving academic success is a challenge for these students as they balance affiliation to home cultures and participation in schools and communities; and ways in which academic performance is challenged by differences in expectations, behaviors, and practices between school educators and families of immigrant and minority students.

There is a large body of research literature on the experience of African American students inside and outside schools; a growing body of literature addressing the experiences of Hispanic students, including Mexicans, Mexican Americans, Puerto Ricans, Cubans, Chicanos, and Latinos/as; and research on Aboriginal, Native American, and Inuit students. There is a developing literature on school experiences of Asian students; some highlight diversity between different Asian groups and within group differences. Research on the experience in schools and communities of specific Asian groups such as Cambodian, Hmong, and Vietnamese is growing. Research on the experience of other groups, however, such as Khmer and Tibetans, is relatively sparse.

Much of the research examining the experiences of minority students in North American schools suggests that we may learn more about the complex ways in which identities are coconstructed and shaped in school contexts by acknowledging the ways in which influences may interact rather than dichotomizing perceptions about schooling and identity among immigrant and minority students. Nancy Smith-Hefner conducted a 30-month ethnographic study of female high school Khmer students and their refugee families in metropolitan Boston using interviews and informal conversations to explore cultural and social-historical influences contributing to the disproportionately high number of female Khmer students dropping out of school. Annette Hemmings, in an ethnographic study of Black student communities at two high schools using interviews and observations, examined the interaction of social class, gender, and other factors within the school communities and found that academically successful Black students adapted their behaviors and

attitudes, effectively altering their sense of identity, in an attempt to be accepted by groups they deemed worthy. Rosalie Rolon-Dow conducted interviews and extensive observations and shadowing of nine 7th-grade, female, second-generation Puerto Rican students from low-income homes and their teachers in their urban middle school as part of a 2-year ethnographic study. She explored how images created by and about the girls shaped their schooling experiences and academic success. Rolon-Dow argued that dichotomizing the sexuality of Puerto Rican female students against their intellectual development obscured the complex ways in which identities are coconstructed.

Despite this growing body of literature focused on ethnic groups, there remains much we do not know about the experience of immigrant students of particular racial and language groups in schools. Eugene E. Garcia stated that Hispanics are often presumed to be uniform across the ethnic group and that there is little appreciation for diversity among individuals within the group. For instance, existing stereotypical images of Puerto Rican girls, Black students, and Asian American students, though different in the academic expectations held of them, were as harmful in that expectations were established for students without taking into consideration personal strengths and weaknesses or diversity within the ethnic group.

Similarly, Stacey Lee found that stereotypical ideas about model-minority Asian students overshadowed differences within the ethnic group and subsequently hindered the ability of teachers to assist Asian students who did not fit the stereotypical image. Even students who performed well academically had their achievement and the effort exerted in order to achieve this success. Clara Park, Lin Goodman, and Lee have found that the absence of their experiences and perspectives in literature stands in stark contrast to their growing presence in schools and societies. Further, these students are perceived as having common experiences, backgrounds, aspirations, and stories. The ethnic and cultural diversity within Asian American ethnic and linguistic groups is often obscured and ignored in mainstream scholarship. Some of these groups are either excluded entirely from studies that focus on people of color or compared with European Americans and other minorities. Min

Zhou and James Gatewood have observed that some Asian American students may be double-marginalized—they do not fit in the mainstream, dominant discourse nor do they fit in marginalized minority discourse.

Theresa Ling Yeh, Don T. Nakanishi, and Tina Yamano Nishida indicate that misinterpretation of similar data has led to the stereotyping of Asian Americans as a group of high-achieving students who possess the skills and knowledge needed to succeed at all levels of education. This perception masks the extensive amount of time and effort expended and overshadows the learning needs of those with limited English and a lack of resources and support. Okhee Lee calls for a better understanding of strengths and limitations of Asian students in academic achievement and social and emotional adjustment. In addition, the model minority myth perpetrates resentment and hostility from members of the majority and other minority groups and has also contributed to crimes being committed against Asians.

### Language, Culture, Identity, and Power

Curriculum is a dynamic interplay between experiences of students, teachers, parents, administrators, policy makers, and other stakeholders; content knowledge and pedagogical premises and practices; and cultural, linguistic, sociopolitical, and geographical milieus. To understand this dynamic interplay of immigrant and minority students' experience of curriculum, we need to draw from multiple theories such as John Dewey's theory of experience, culture, and curriculum; Joseph Schwab's eclectic conception of curriculum; Michael Connelly and Jean Clandinin's narrative conception of curriculum; William Schubert's autobiographical reflections and curriculum; William Schubert and William Ayers's teacher or student lore and curriculum; and Geneva Gay and Gloria Ladson-Billings's multicultural-critical multicultural perspectives of curriculum. Immigrant and minority students enter curriculum situations with experiences, cultures, and languages different than their own and encounter places as strange as new countries, communities, and schools.

Language, culture, identity, and power, which often lead to controversies in research, policy, and

practice, are the key terms to explore the diversity and complexity of education of immigrant and minority students' experience of curriculum. Key language issues center on English language learning and heritage language maintenance, English as a second language education and culturally incongruent curriculum, length of time to attain academic English proficiency, and English proficiency and academic achievement. Closely related to language issues are culture issues that include cultural discontinuity between homes, schools, and communities; cultural incompatibility in learning and teaching styles; and race, gender, and class.

Issues of language and culture are at the center of controversy over identity. Key identity issues recognize identity as complex, fluid, and changing over time and place; developed in relationship with peers, teachers, parents, and grandparents; shaped by ethnic groups to which immigrant students belong and societal perceptions of specific ethnic groups; and impacted by sociopolitical and cultural contexts. The term *power* overarches and permeates research on language, culture, and identity. Research on power issues includes the marginalization and disempowerment of minorities, racism, poverty, educational inequalities, and critical pedagogy.

Language, culture, identity, and power are closely interconnected in immigrant and minority students' experience of curriculum inside and outside schools. For instance, research indicates that heritage language maintenance and bilingual education support English language acquisition that helps develop self-esteem and contributes to school success. To learn English in order to be accepted by their English-speaking peers, North American-born children of immigrants in Sandra Kouritzin's study later regretted their limited ability to speak their heritage languages. Those who abandoned their heritage languages to overcome initial exclusion from North American peer groups due to their inability to speak English later felt excluded from their ethnic communities due to their inability to communicate in their heritage languages. Their English and heritage language proficiencies shaped their sense of identity and belonging in their ethnic communities and North American society.

Acknowledgment and inclusion of diverse cultures and languages in school contexts are central to promoting immigrant students' school success.

In a critical ethnographic study on the literacy development of immigrant children in her own classroom, Cristina Igoa found that the inclusion of home languages and cultures in classroom activities and lessons had positive effects on students' sense of belonging in their new U.S. classrooms and their sense of identity as members of a U.S. school community and an ethnic community. Igoa argues that cultural resources children of diverse backgrounds bring into classrooms contribute to their social and academic development rather than being detrimental to their academic success and adjustment to school life.

Lily Wong-Fillmore's work also addresses the detrimental effects of heritage language loss on families and ethnic minority communities when parents, who are not fluent in English, lose the ability to communicate with, guide, and teach their children. Wong-Fillmore examined the role of schools in contributing to the heritage language loss of children of immigrant and minority families. She found that some children in her study had teachers who advised parents to speak to them in English rather than in their home languages, even when parents were not proficient in English. She highlighted the important role of educators in preventing heritage language loss by supporting its maintenance. Jim Cummins strongly advocates for the inclusion of ethnic cultures and languages in the classroom. He argues that heritage language proficiency is a distinct advantage as knowledge of language structures and components in the heritage language may be transferred to enhance the acquisition of English. This phenomenon, referred to as the linguistic interdependence principle, provides evidence against practices of encouraging ethnic minorities to abandon heritage languages in favor of English only.

Other research demonstrates that immigrant and minority students are more likely to succeed in school settings when they are not alienated from their cultural values. The lack of acknowledgment for home cultures was also identified as contributing to the high dropout rate among Latino/a students in Virginia Zanger's study of the schooling experience of academically successful and unsuccessful Latino/a high school students. Martha Hertzberg, in her study of Mexican and Latino/a students, found that a nurturing school setting with culturally flexible teaching that validated

linguistic and cultural diversity contributed to the educational success of immigrant students.

Cummins emphasizes the role of language and culture at school and home in shaping immigrant students' identities. In his work, language, culture, identity, and power are intertwined. Immigrant and minority students felt that they did not have a sense of belonging when their heritage languages and cultures were not acknowledged in schools, more specifically, not incorporated in regular classroom activities. The academic success and subsequent career success of immigrant and minority students were jeopardized when the curriculum did not draw on the linguistic and cultural knowledge they brought to school. Incorporating immigrant students' linguistic and cultural knowledge in school curriculum creates an empowering school environment where immigrant students have a sense of belonging, feel proud of their heritage languages and cultures, and experience learning situations in which they are able to succeed. Language, culture, identity, and power, which are deeply embedded and interconnected in life, are the curricula immigrant and minority students experience in schools, families, and communities.

Immigrant and minority students encounter many challenges: unresponsive teachers who are ignorant about or disinterested in students' experience of language, culture, identity, and power; disempowering curricula that negate or as Angela Valenzuela stated, subtract their experience; identities derived from generalizations and stereotypes imposed by societies, schools, and peers; and disempowered or marginalized parents, as those portrayed in Chris Carger's work, in spite of their best intentions and strong desire for their children to succeed, due to incongruity between educational expectations in their home cultures and their new school cultures and difficulties in expressing knowledge due to differences in language, class, and education systems.

### A Curriculum of Shared Interests

Drawing from their research on immigrant and minority students' experience of curriculum, Ming Fang He, JoAnn Phillion, and Elaine Chan have found that there is a demand for a curriculum of shared interests where all members of the school community and policy-making milieu

have common concerns. Families connect their concerns about the education of their children with those of the larger society. Schools share their interests in educating immigrant students with families and communities. Individuals have equal opportunities, as Dewey stated, to take and receive from others and to have free interchange of varying modes of life experience, and they are willing to adjust their interests to the interests of others in the larger society. In such a curriculum of shared interests, teachers recognize contributions of ethnically and linguistically diverse students and develop cultural and pedagogical competence to enrich the curriculum for all. Students are encouraged to value their cultural and linguistic heritages, respect and accept differences, critically examine their positions in local and global communities, and perceive themselves as agents of positive curriculum change. Policy makers and administrators learn the nuances of immigrant and minority students' experience of curriculum; value the knowledge held by teachers, students, parents, and other curriculum stakeholders; and incorporate this knowledge into policy-making. Families and communities share responsibility with schools and government organizations to create a school environment that is equitable, safe, caring, and inspiring. This milieu cultivates a curriculum of shared interests that commits to a high level of achievement, not just for immigrant and minority students, but for all. Such a milieu could be expanded to a global human condition that encourages inclusion and participation of all citizens; guarantees respect, innovation, interaction, cohesion, justice, and peace; and flourishes with cultural, linguistic, intellectual, and ecological diversity and complexity—the common heritage of humanity.

## INCLUSION

---

Inclusion represents a philosophical and administrative-curricular practice that places students with special needs in the general educational setting of the school as opposed to placing students in a self-contained classroom. Two central questions in curriculum studies have long been associated with the concept of inclusion: For whom are we designing school curricula and toward what ends? The movement for inclusive schools, classrooms, and practices brings these questions into sharp relief. To understand the inclusive schools movement, it is helpful to first examine the long history of exclusion that characterizes much of the history of schooling. Schools and school curricula have often acted as what Joel Spring calls sorting machines, and nowhere is this more evident than in the exclusion of students with disabilities from formal public schooling or in the subsequent creation of segregated, self-contained special education schools and classrooms. In these special education classrooms, students with similar educational needs are grouped together and educated separately from their typically developing peers.

In the United States, special education was codified by Public Law 94-142 in 1975 and guaranteed every child with a disability access to a free and appropriate public education in the least restrictive environment. Thus, in the 1970s, schools were required to place children with disabilities in the mainstream of public education as long as the student could be successful in these general education settings. This frequently meant that students attended nonacademic subjects with their typically developing peers or were mainstreamed for subjects such as art and music. Not satisfied with either separate education or this partial access, parents and people with disabilities began to push for full inclusion of all students with disabilities into general education settings,

with special education supports and services provided in the general education setting.

However, the distinction between inclusive schooling and special education is less a question of delivery of services model and more a matter of paradigm and orientation—that is, self-contained special education is based on a medical model of disability that attempts to diagnose the student's underlying problem, produce the correct label for the person (such as learning disabled, autistic, developmentally disabled), and then make an individual plan to remediate the problems. Inclusive schooling, however, emerges from a social model of disability that asserts that the category of normal—as in free from difference—is suspect. Impairment is not denied (e.g., paralysis is real), but its complications stem mostly from socially constructed barriers and attitudes. Disability can give rise to particular subject positions that inform one's identity and perspective. Thus, disability is an aspect of a person's identity, not all encompassing, but one part along with race, ethnicity, class, gender, socioeconomic status, religious beliefs, sexual orientation, and countless other ways people are both different from and the same as one another.

In the United States, inclusive education emerged out of the separate bureaucratic structures of the special education system and has focused primarily on issues of access to the general curriculum (first in terms of physical proximity or placement in general education classrooms and subsequently in terms of meaningful participation in general education curriculum) for students with labeled disabilities. However, a broader, worldwide movement toward inclusive schooling has drawn upon both curriculum studies and disability studies frameworks to inform emerging understandings of inclusive education as necessarily involving active and deliberate transformation of schooling as a whole (in closer alignment with United Nations Educational, Scientific, and Cultural Organization's usage of the term). In this broader context, inclusive education seeks to resist and redress the many ways in which students experience marginalization and exclusion in schools. Inclusive teaching and schooling work to actively resist and dismantle the many sociocultural, institutional, bureaucratic, and interpersonal ways in which students and their families experience marginalization and

exclusion in schools (e.g., on the basis of race, ethnicity, social class, dis/ability, gender, nationality, sexuality, language, religious [non]affiliation, etc.). This usage of the term inclusive education does not trace its discursive lineage directly from special education; rather, it emerges from a variety of broader policy and reform agendas, including a variety of traditions of anti-bias and democratic curricula.

## INDIGENOUS LEARNER

---

Indigenous learners are members of sovereign nations, speakers of heritage languages, and members of diverse cultural groups. Indigenous learners include Australian aborigines, New Zealand Māoris, American Indians, and Alaska Natives as well as members of nearly 5,000 different indigenous groups from around the world. The field of curriculum studies recognizes indigenous learners as culturally and politically situated members of sovereign nations and diverse culture groups. Curriculum studies explores the relationship between school programs and the society and culture in which the school is located. Although the majority of these nearly 6 million indigenous peoples retain languages, social customs, economies, and spiritual beliefs and although individual indigenous learners demonstrate preferred learning styles, there is no single adequate description

of the indigenous learner and no one way of describing classroom interactions with indigenous learners in terms of learning styles, cultural values, and teaching styles.

American Indians and Alaska Natives make up only 1% of the total U.S. population. They account for 50% of the different languages spoken in the United States. Although American Indian students enter kindergarten with significantly lower reading, mathematics, and general knowledge achievement scores than their mainstream peers, there is evidence that these indigenous learners learn best when they see their culture, language, and experience reflected in the curriculum. Native American children who learn their heritage language in the classroom learn English at about the same rate as their peers who are not enrolled in an indigenous language immersion program.

American Indians have a unique status as sovereign nations within a nation. The treaty rights guaranteed to American Indians in Article II of the U.S. Constitution are the foundation for federally operated schools that serve American Indian students. The majority of American Indian students, 624,000, attend public schools in urban settings or on Indian reservations. The Bureau of Indian Education (BIE) operates 184 schools on 63 reservations representing 238 tribes. The BIE is one of only two educational systems administered directly by the U.S. government and the only federal educational system in the continental United States. BIE schools include boarding schools, high schools, border town dormitories, reservation dormitories, and day schools. Indigenous learners also attend tribal contract or grant schools that are managed by a local school board in accordance with the 1988 Indian Self Determination Act and the Tribally Controlled Schools Act. They may also attend public schools that receive federal impact aid funds as well as state tax revenue funds. There are also 35 tribal colleges that serve adult learners on or near Indian reservations.

The history of formal education for the indigenous peoples of the Pacific—New Zealand, Australia, and Hawai'i—parallels the history of education of the American Indian. In New Zealand, the Native Schools Act of 1887 made English part of all government schools. In Hawai'i, the Hawaiian language was banned in public and private schools between 1886 and 1986. In Canada,

the Indian Education Act of 1876 began a policy of forced assimilation and separation from their families for indigenous learners. In the United States, in 1868, the Indian Peace Commission advocated the eradication of indigenous languages and the substitution of the English language. In each setting, efforts to revitalize the indigenous language come from an understanding of the history of formal education in colonial times as well as an understanding of the indigenous learner. Without this understanding of the history of education, indigenous learners are often faced with cultural replication models of schooling that lead to a false assumption that they must act White in order to achieve academic success.

The United Nations Declaration of Human Rights guarantees parents the right to choose the kind of education that shall be given to their children. The rights of indigenous learners are further guaranteed by the 1992 United Nations Declaration on the Rights of Persons Belonging to National or Ethnic, Religious and Linguistic Minorities that mandates that states protect the existence and the national or ethnic, cultural, or religious and ethnic identity of minorities within their respective territories and that states encourage conditions for the promotion of that identity.

In New Zealand, in the 1980s, the effort to reverse language shift began in the early childhood setting with the institution of the *kohanga reo* (language nests), a full immersion program for preschool indigenous learners. Today 14% of the Māori population speaks the Māori language well or very well. In 1983, Hawaiian educators founded the Punana Leo preschools that provided full-day, year-round Hawaiian-language preschools. In Canada, in the community of Cold Lake, Alberta, projects to reverse language shift include full immersion day care and full immersion Canadian Head Start programs. In the United States, Rough Rock Demonstration School on the Navajo Nation, which opened on July 27, 1966, was the first school to be governed by an all-Indian, locally elected school board. The Rough Rock school focused on community development as on a culturally relevant curriculum. Each of these exemplary programs—the Māori Immersion Program; the Hawaiian Immersion Program; the Cold Lake Alberta, Immersion Day Care; and the Rough Rock Demonstration School—meets the needs of

the indigenous learner through the recognition and use of the native language, a curriculum and pedagogy based on traditional culture, teaching strategies based on traditional ways of knowing, a strong native community participation in education, and an understanding of the political processes in the community.

Indigenous learners bring cultural and linguistic diversity to U.S. classrooms. The languages and cultures of American Indians and Alaska Natives are unique, and the history of the education of indigenous learners is a foundation for understanding U.S. history and for understanding the issues that limit academic achievement for all rural minority students.

The curriculum that meets the needs of indigenous learners includes hands-on learning, student choice, support from the indigenous language and culture, and an understanding of the contributions of American Indians to U.S. society. In the classroom, indigenous learners seek a balance between themselves and their communities. The indigenous learner often demonstrates learning styles that are holistic, visual, and cooperative. The indigenous learner learns by observing and by working as an apprentice to more proficient peers. A culturally responsive curriculum prepares indigenous learners for later academic success as well as for citizenship in local, tribal, and global communities.

## INDIGENOUS RESEARCH

---

Just as curriculum studies encompasses the curriculum as culturally and politically situated, indigenous research is grounded in the social-historical conditions of the indigenous community and in the positionality of the indigenous researcher as a member of the community. Linda Tuhiwai Smith describes the work of the indigenous researcher in framing the research question in terms of indigenous politics and cultural action. Whose questions are posed? Whose interests does the research serve? Who will reflect on the significance of the research? Who will share the research? Indigenous research seeks to deconstruct the Eurocentric models of the past and to regain the critical consciousness of the cultural, historical, and linguistic roots of indigenous peoples. Indigenous research regains this critical consciousness through the teachings, stories, and actions of indigenous peoples in their schools and in their communities. The transformative knowledge gained from this fresh view of the curriculum supports quality education for native communities.

### Themes and Knowledge Systems

Indigenous research includes themes in education that are repeated across communities and across educational institutions. These themes include the history of indigenous schooling, the history of formal schooling including organizational structures in schools and governance of schools, school funding and funding for indigenous populations, language shift, language revitalization, curriculum and pedagogy in schools serving indigenous learners and demographic trends in schools serving indigenous learners, student academic achievement, retention, graduation rates and violence in schools, teacher preparation and teacher induction in indigenous communities, and factors the community that support school success.

Indigenous research includes the documentation and articulation of indigenous knowledge systems. This research is based on ethical rights of cultural and intellectual property and the oral tradition that is based on reciprocity, trust, and cultural and linguistic knowledge within the community. Beth Leonard discusses issues of the

ethical use of recordings of her native Deg Xinag language and issues of cultural rights when she questioned speakers of her ancestral language during her research. This articulation of this knowledge system is framed within the oral tradition, a tradition that is a way of sharing stories and sharing reciprocal relations of trust. Through the oral tradition, indigenous knowledge is transmitted from generation to generation. This oral tradition includes the knowledge of elders, knowledge of the environment, knowledge of traditional economies including food preparation, healing, and child rearing skills. Indigenous research strengthens the oral tradition and supports the efforts of indigenous peoples to record cultural and linguistic knowledge. The 2007 United Nations Declaration on the Rights of Indigenous Peoples recognizes the rights of indigenous peoples to develop their intellectual property through traditional knowledge and cultural expression.

### Processes

#### *Narrative*

Indigenous research is undertaken through narrative inquiry. The researcher begins with an unstructured oral interview with a member of the indigenous community. The interview is transcribed, and the transcripts of the interview are given to participants. The transcripts are discussed and become a part of the ongoing record. The indigenous participant researcher builds a sense of the whole from this rich data source that focuses on concrete events in the stories of the participants. As a participant researcher, the indigenous researcher critiques outsider interpretations. The text of the interview challenges and moves the thinking of researcher and the participants beyond their understanding when the dialogue began. Indigenous narrative research explores the institutions of literacy and power in which indigenous teachers work and live. The researcher listens for the unique stories of how teachers learned to value their language and why they continue to teach it. Each teacher understands the history of indigenous language literacy in a different way; each teacher passes this understanding on to his or her students in a different way. These stories are invitations for all teachers to give voice to their histories and memories. An understanding of these beliefs about

how indigenous language will continue in future generations supports the autonomy of teachers and community members to reverse language shift.

### *Participatory*

Greg Cajete further describes indigenous research as participatory research. He writes of Paolo Freire's view of a participatory relationship with the natural, cultural, and historical reality of the community. The process of indigenous research calls for participants to create new meanings and to apply insights gained from their research to their lives. Through this process of indigenous research, teachers become agents of change in their schools and their communities as they understand their current condition and as they change these institutions from within.

### *Ways of Knowing*

Indigenous research includes the study of learning processes associated with indigenous ways of knowing as well as with the customs, language, and cultural values of the community. In Chinle, a community on the Navajo Nation in Arizona where there are no sidewalks or milepost markers, students measure the distance to school in terms of fenceposts or landmarks. Indigenous research includes the study of learning style preferences that may be visual or holistic. Indigenous research describes how the indigenous learner observes, then practices a new skill with the support of a more proficient mentor. Indigenous research includes the study of ethno-science, the theories and procedures for learning about the physical world that have evolved within cultures and that explain and predict natural phenomena. Indigenous research includes the study of ethnomathematics that explores the mathematical ideas that have evolved within cultures. For example, when students in Chinle who have learned traditional string games explore the concept of axial symmetry in geometry through reversing the steps in creating string figure, they demonstrate mathematical skills through their traditional cultural knowledge.

Indigenous research includes the process of developing and assessing educational strategies integrating indigenous and Western ways of knowing. These strategies include both classroom

interactions and groupings as well as teaching strategies; indigenous research explores how students connect prior knowledge to new academic knowledge, how students solve problems, and how students learn and retain new academic content knowledge. These strategies are observed and analyzed within the sociocultural context of the school, the family, and the indigenous community.

### **Results and Benefits**

Indigenous research helps members of the community reflect on their knowledge and on the worldview of the community. Indigenous research restores autonomy to the community and describes how knowledge is transmitted across generations. This research answers the questions: Whose knowledge is valued? What knowledge is taught? These questions describe the process of the creation of new transformative knowledge. This research begins with the personal and cultural knowledge of the community and with the research questions of the community. Ray Barnhardt and Oscar Kawagley call for an indigenous research agenda in which researchers respond to requests from the community and collaborate to solve problems. From this research, new transformative knowledge is constructed that can be shared in broader social political contexts. Barnhardt and Kawagley use the example of a story told by an Inupiak elder who described how his father taught him to hunt caribou with a bow and arrow by walking directly into the herd, then slowly imitating a giant bird that attracted the caribou to his waiting bow and arrow. The story illustrated the strong connection between the hunter and his prey; a connection that was no longer necessary when hunters used modern technology—for example, rifles. This story also illustrated the way the indigenous researcher approached the topic of the discussion of ways of privileging indigenous knowledge in the curriculum. This indigenous knowledge is based on a sense of place and on an oral tradition that values the master-apprentice model of teaching in authentic settings.

Indigenous research provides a fresh view of the process of knowledge construction. One example of this circular perspective is the Diné education philosophy. The Diné education philosophy is a transformative knowledge contraction process.

The first stage is thinking Nitsáhakees. At this stage the researcher begins with an awareness of the process of critical investigation. The direction of this stage is the east. The direction of the next stage in research is the south: Nahat'á (i.e., planning). At this stage the researcher identifies resources and sources for investigation. The third stage is the west: Líná (i.e., life). At this stage the researcher applies ideas and gains new information. The fourth stage is the north: Siihasin (i.e., stability). At this stage the researcher evaluates and assesses his or her satisfaction with the research and prepares to formulate new research questions. This framework is used in research to connect personal and cultural knowledge, stories, experiences, and social interactions.

Indigenous research returns to the community as both the sociohistorical foundation for new research and new indigenous knowledge and as the audience for sharing this knowledge for purposes of social justice within the community. The researcher views the community from a fresh vantage point, from the perspective of those who hold knowledge. The researcher describes how this knowledge is transmitted in learning communities that include schools, clans, recreational organizations, agricultural units, or religious institutions. Marie Battiste proposes that indigenous research provides insights that transcend Eurocentric theory and that valorizes the resilience and self-reliance of indigenous schools and communities.

K. Tsianina Loawaima and Teresa L. McCarty describe the historical perspective of indigenous research as a contest among sovereignties: the right of a people to self-government, self-determination, and self-education. This historical research includes discussions of linguistic and cultural rights and social reproduction produced by an entrenched federal bureaucracy. Their research questions which aspects of Indian education are safe enough to be included in the curriculum and which are seen as in need of assimilation. Indigenous research in the history of education documents research on American Indian places of difference within the history of U.S. education. Rough Rock Demonstration School, which opened in 1966, was the first school to be governed by an all-Indian locally elected board. The school was regarded not just as a place for educating Indian children, but as the focus for development of the local community. At

Rough Rock there was an emphasis on community control of the school. In the classroom, students were exposed to a bilingual-bicultural curriculum. The curriculum was developed to instill in the students a sense of pride in being Indian and to show them that they could take the best of each way of life and combine them into something visible. In 1983, Rough Rock Demonstration School adopted a new bilingual-bicultural curriculum based on the an inquiry-based social studies curriculum that followed a spiraling sequence of culturally relevant topics beginning with the Navajo concept of *ke'e* (i.e., kinship). The Rough Rock Demonstration School thus provided a model for contract schools that were locally controlled and that became centers for the development and dissemination of Navajo language curriculum materials. Indigenous researchers explore this history to understand how schools can be repositioned as agents of change in the revitalization of indigenous languages and cultures. Indigenous research describes the forces of standardization in schools serving indigenous learners that stratify, segregate, and limit equality of opportunity in indigenous communities.

### Role of the Researcher and the Indigenous Community

The indigenous researcher has a responsibility to the community that includes a responsibility to return conclusions to the community and to synthesize these conclusions with ongoing curriculum and pedagogy to restructure the school to put this new transformative knowledge into practice. This knowledge is based on the premises that education is best when it reflects a sense of place, that education should be based on the philosophy and values of those being educated, and that indigenous research should reflect the perspective on education of the community. Robert Yazzie recounts his own experience of returning to the Navajo reservation to make changes based on his Eurocentric education. Yazzie found that his position of authority in the community where he sought transformation required that he relearn his language and return to the traditions of his community. Mary Hermes writes of returning to the Lac Coudre Ojibwe reservation to create a culture-based curriculum in a tribal school. Her research brought

together the perspectives of community members, her personal experiences and narratives as a teacher, and her experiences as a researcher and as a doctoral student around the research question of the meaning of school in her community. Hermes was a community member first and a researcher second. For Hermes, indigenous research became a recursive process situated within the classroom and the community. Jessica Ball demonstrates that a generative curriculum model supports the indigenous community and controls the teaching of young children within the school and the community. In Ball's research in First Nations communities in Canada, Cree teachers learned to use their voice as indigenous peoples, to evaluate Western ideas, and to create models to promote the cultural and linguistic identities of their children.

Graham Smith calls for indigenous research to adopt a transformative process for the protection and respect of indigenous knowledge. He calls for indigenous people to engage in naming the world in a way that claims responsibility for sites of possibility and change in indigenous communities. He calls for indigenous researchers to take action that meets the needs and aspirations of indigenous teachers and community members. He calls for indigenous researchers to reclaim their own lives through the process of participant research: to take control of their own destinies. Smith calls for indigenous researchers to resist an uncritical focus on Eurocentric positivistic science and to include the study of ethnohistory and ethnomathematics in the curriculum.

Indigenous research is not exploited, oppressed, or subordinate. Indigenous peoples may be in the numerical minority, yet their history and culture are resources that enrich all curriculum. Indigenous research must critique the romantic and the over-generalized and develop transformative outcomes for the indigenous communities in which research is conducted. Indigenous research is accountable to both the academy and to the indigenous community.

Indigenous communities must examine their own skepticism toward research and educational theory and continue to develop an interface between indigenous knowledge and practice in the classroom that serves indigenous learners. Indigenous research must work to transform the community. This research is based on indigenous values that

recognize the collective solidarity of family, clan, and culture. Indigenous research is based on values and practices that transform the relations of power and ideology within the institution of the school. Indigenous research is based on the values of social justice in indigenous communities.

Indigenous research is positioned within the local indigenous community and shares this local knowledge with other indigenous researchers in other communities as a process of researching back. This researching back, the critical consciousness of the cultural and historical roots of indigenous peoples as understood and expressed by them, is the foundation for the cultural emancipation of indigenous peoples.

## INDIVIDUALIZED EDUCATION— CURRICULUM PROGRAMS

---

Within the field of curriculum studies, individualized education programs has a meaning different from mainstream uses of the term *individualized education programs* (IEP). In the United States, an IEP is a specific written statement for every student with disabilities that is produced, reviewed, and consequently revised within under the purview of the federal Individuals with Disabilities Education Act (IDEA). However, because individuality and the importance of students-as-individuals are paramount American values, there are a multiplicity of connections between curriculum, programs, and the individuals who are their intended audience.

The individual needs of students is therefore a fairly wide and far-reaching category. Curricular programs designed in response to students' individualized educational needs lie at the heart of a central tension in curriculum studies: how to provide all students with an equal education while simultaneously tailoring curricular contexts to individual student's social, academic, and emotional needs. As such, these diverse and occasionally disparate perspectives can be examined as questions of curriculum differentiation: how do curricular programs respond to students' individualized educational needs?

On its surface, individualized education corresponds to singular person's educational needs. However, individual student's particular racial, gender, class, or other such attributes can become the focus of a particular local policy or pedagogical

practice. For example, in many large school districts where students speak a language other than English at home or in their communities, there are educational programs designed to assess individual student's current fluency in English and to measure their progress toward a native speaker's level of grade-appropriate fluency. The possibilities for an unintentional or intentional disabling of nonmainstream students by language is a well-traveled road represented by such strong scholarship as by Lisa Deplit and Joanne Kilgour-Dowdy, Shirley Brice Heath, and Katherine Au. Their works share an understanding of how sociocultural aspects of individuals such as language (or race, class, gender, sexual orientation) can be retooled as individual deficits.

Similarly, there is a body of literature that illustrates how the particularized attention given to individuals with perceived disabilities has a tendency toward self-fulfilling prophecy that reifies students' disabled status in the course of providing the individualized programs students require. Harlan Lane's discussion of schooling and deaf students in *The Mask of Benevolence: Disabling the Deaf Community* and Harve Varenne and Ray McDermott's presentation of how children acquire a learning disability in *Successful Failure: The Schools America Builds* are examples of such scholarship. Varenne and McDermott's argument that academic differences are recast as disability and disability is located not within the child, but outside of him or her in the educational definitions and systems that contextualize a child's schooling is particularly germane to this discussion.

Finally, there is yet another body of literature that addresses formalized curricular differentiation at the school and district level. In order to meet student's individualized educational needs, schools regularly offer different levels of academic content to the same-aged students. Work by scholars such as by Jeannie Oakes documents how difference as deficit can negatively impact the curriculum and pedagogy students receive in an effort to provide them with the academic content thought to suit their particular needs. While confirming these tendencies, Reba N. Page and Linda Valli have complicated this curricular conversation. Their work empirically documents how curricular differentiation can, but does not always

negatively impact students perceived to be less academically capable and how students who might be considered capable in one context are seen as less than adequate in another.

Individualized education lies at the heart of much of curriculum studies. As briefly documented in this entry, efforts to individualize education through various curricular programs can also serve to differentiate children, negatively impacting traditionally marginalized student populations including, but not exclusive to those who would receive IEPs under the IDEA.

## INDOCTRINATION

---

Indoctrination represents a classic dilemma in the field of curriculum studies and raises the issue of whether all acts of teaching impose content, perspective, or values. In essence, indoctrination refers to both a normative belief that teachers should impose good values on students and an empirical belief that schools do in fact impose values on students. The term, however, took on specific historical significance as an ideological stance for educators from the early-to-mid 20th century who maintained that schools should serve as a tool for the reconstruction of society and should engage in the indoctrination of students.

Concerns of indoctrination have more recently justified the importance of examining programs of study to ascertain the reproduction of knowledge, social control, and the hidden curriculum.

Viewed at the most fundamental level, the selection of content for any program of study may be seen implicitly or explicitly as a gesture of indoctrination in either a benevolent sense or as an act of oppression. Such perspectives have created a contested conception of the purposes and mission of education, curriculum design, and curriculum development. Indoctrination became an idiosyncratic professional term due to a 1932 Progressive Education Association (PEA) conference presentation by George S. Counts. In “Dare Progressive Education Be Progressive,” Counts challenged educators to use schools as a means to openly indoctrinate a positive social vision and to combat negative forces of society by indoctrinating students against indoctrination. This presentation along with two other speeches by Counts was published in 1932 under the title *Dare the School Build a New Social Order?* ushering in a social reconstructionist perspective within the PEA. The topic became most problematic when designing progressive education curricula since educators questioned whether the teaching of democratic values represented a form of indoctrination. Yet to not endorse the fostering of democracy as a purpose of schooling indicated an inability to define an adequate social philosophy sufficient for guiding action and determining the curriculum.

Indoctrination took form of “the imposition controversy” when Boyd H. Bode and John Childs published an exchange of articles in the *Social Frontier* between 1935 and 1938. Childs (expanding Counts’s social reconstructionist position) called upon educators to develop curricula with distinct social ends. Bode maintained, however, if such social ends were predetermined and the schools became the means for their implementation, this was a form of dogmatism and authoritarianism, anathema to democracy. The spirit of free inquiry and democracy could not be embraced by schools if social ends had already been determined. Childs countered by acknowledging the fundamental biases inherent in all school settings and viewed education as implicitly and necessarily partisan. Values were already being imposed in the

educational system, Childs maintained, and teachers were irresponsible if they did not examine and then emphasize more appropriate values. Bode objected, asserting that any imposition of values represented an abomination to democracy; he asked educators to trust democracy by maintaining faith in the general sensibilities of the common person. Bode's position did not particularly satisfy the many social reconstructionists calling for societal reform, and the ultimate demise of the PEA has been attributed, in part, to differences arising from this issue.

Theodore Brameld later attempted to reconcile the imposition controversy as a component of an educational reconstructionist position. While objecting to indoctrination, he believed teachers should be willing to discuss ideology in the classroom. Only through open discourse and the critical examination of ideas could teachers hold beliefs that were also defensible. Brameld proposed the concept of defensible partiality, developed from a Minnesota curriculum project, where ends and means would be regularly critiqued in open discourse, and if able to withstand such criticism, then ideological positions could be openly advocated without rigidity or indoctrination. The discussion and critique of ideas became, for Brameld, a commonplace and mandatory activity of schooling in order to establish defensible partiality. Yet neither did defensible partiality resolve the dilemma, and educators continue to struggle with issues of indoctrination and the implicit and explicit imposition of content, perspective, and values in the curriculum.

## INFORMAL CURRICULUM

---

There are multiple perspectives in the field of curriculum studies regarding definitions of curriculum. This variation is particularly the case when curriculum is qualified with a descriptor. In the case of the term *informal curriculum*, the usage also varies although most commonly it is contrasted to that of formal curriculum. The formal curriculum is the material and content explicitly taught in schools. This curriculum is inclusive of state guidelines and the accompanying material to be disseminated from a teacher to students in classrooms. The teaching associated with the formal curriculum is generally guided by scope and sequence that drive lesson planning. Often instruction for pupils in classrooms is based on what educational governing bodies in individual states have determined should be taught in individual grade levels. When curriculum falls outside of the prescriptive, planned teaching and learning of the formal curriculum, it can be considered part of the informal curriculum. Differing meanings of informal curriculum can be grouped into several categories: the unofficial learning occurring in schools, extracurricular activities happening in school settings, and curricula happening outside of school.

The tremendous amount of information learned in schools that does not occur through explicit instruction is a component of the informal curriculum. This learning is not planned or agreed upon by teachers or governing education bodies; it is perceived as unofficial. The informal curriculum in this context is not orchestrated because it focuses on the spaces that happen in between delivery or structure associated with the formal curriculum. This view of informal curriculum directly results from decisions made in determining the formal curriculum. For instance, different school subject areas given more time and provided with more resources informs without the explicit objective of doing so. The values associated with different types of learning can be viewed as an informal curriculum since those in schools gain understanding or draw meaning as a result. Further, the importance of specific content and the way the formal curriculum is taught becomes a dimension of informal curriculum. How teachers view students in respect to what is being taught, coupled with

teachers' ideological frameworks, become integral components of informal curriculum.

Although this curriculum is ungraded, students' school experiences are greatly affected by it. Lesson plans associated with formal curricula scope and sequence are absent in the informal curriculum. Class schedules, available resources, or inclusion-exclusion of viewpoints contribute to this unplanned learning. The informal curriculum includes ability grouping based on perceived aptitude since it places value on who should learn, what they should learn, and how they may be able to learn. Inevitably, school culture including expectations and roles of teachers, students, administrators, parents, and the community all are part of informal curriculum. For instance, are students allowed to use restrooms on their own? Do children march down hallways single file? Are some subjects favored over others by giving more time to them? Are some subjects not taught at all? Does testing drive content in the classrooms or is it based on student interests? These elements of the curriculum teach without the intentions scripted through formal instruction.

Because of the nature of learning outside of the formal curriculum, a related usage of informal curriculum is related to extracurricular activities. *Extracurricular* infers that the activities are not related to or are over and above the formal curriculum. Some informal curriculum activities are associated with voluntary time spent in schools including lunchtime, afterschool programs, team sports, and clubs. Many curriculum scholars contend these should not be seen as separate entities of formal curricula because they play important roles in what happens to students in school and the resultant learning that occurs.

Yet another viewpoint of informal curriculum has to do with the learning happening absent from the confines of school altogether. Transcending school structures, learning occurring in these spaces is also informal. Sometimes called the outside or out-of-school curriculum, this kind of learning occurs both regularly and irregularly throughout one's life. These learning experiences associated with the informal curriculum occur in neighborhoods, communities, and the family. In this sense, the curriculum incorporates what happens through popular culture, commercialized spaces, the Internet, museums, parks, peer groups,

social events, and civic engagement because resultant learning happens, albeit largely unrecognized in school settings.

## INSTITUTIONALIZED TEXT PERSPECTIVES

---

Institutionalized text perspectives can be understood as an answer to the following question: What does institutionalized text mean and for whom do such meanings count? The answers to this question are highly dependent upon how one defines text. In curriculum studies, constructions of text in general and of institutionalized text in specific most often fall under two overarching categories. On one hand are those scholars such as Suzanne deCastell, Michael W. Apple, and Linda Christian-Smith whose work has focused on critical examinations of textbooks used by teachers and students in classrooms. On the other are scholars such as William F. Pinar, William Reynolds, Patrick Slattery, and Peter Taubman's *Understanding Curriculum*, a work that is organized according to how curriculum scholars read sociocultural interactions, tendencies, and implicit norms and values as text. However, whether institutionalized text is understood as (a) the textbooks that are written and approved by institutions or (b) the ways in which sociocultural precepts—race, class, gender, sexual orientation, and perceived ability, for example—can be critically examined in a fashion similar to a written text, the tendency in curriculum studies is the careful,

discerning examination of how, for whom, and to what possible ends such texts are constructed.

Although there are other possible constructions of institutionalization that fall under the umbrella of curriculum studies, use of the term institutionalized in the field of curriculum more often refers to the scholar's work that ascribes to the following characteristics. This work critically examines the role of schools in relation to society; the ways that dominant norms and values inform schools, classrooms, teachers, and students; how schools as institutions of the state promulgate these views; and the ideas and ideals of those in power of a given nation-state.

In light of the above understandings, this entry is organized into two overarching halves. The first half addresses institutionalized text perspectives as they relate to the written word, focusing on textbooks, their content, and usage. The second considers institutionalized text as the ways in which scholars have critically explored the relationships between school actors and the institutionalizing nature of schooling. Although institutionalism in curriculum studies most often refers to social reproduction, enforcement, and the legitimization of sociocultural norms and values, both sections address questions of text according to this perspective.

### Textbooks as Institutionalized Texts

The consideration of textbooks as institutionalized texts can be understood as a Venn diagram sharing concepts with at least two other entries in this encyclopedia: official knowledge and formal curriculum. This entry focuses on work that highlights the institutionalizing nature of textbooks. As with all aspects of curriculum, textbooks are inherently both academic and social. The knowledge presented in textbooks is not the content on a given topic, idea, or ideal, but one construction among myriad possibilities for expressing knowledge. In an academic year, there are limitations of time, a multitude of ideas surrounding a given concept or construct that need to be presented, and an equally large number of possible contexts that influence and are influenced by a particular concept or construct. That textbooks focus on a given set of knowledge in a particular order and fashion is both a theoretical and a practical necessity.

The ways in which textbooks are organized, the content they convey, and the kinds of teaching that their organization and content engender reflect not only what counts as knowledge in a given society, but also what information about students and their relationships to others is communicated. As embodiments of purposefully compiled state- and district-sanctioned knowledge to be delivered to students in schools, textbooks are literal incarnations of institutionalized (state, local governmental agencies, schools) texts.

Textbooks therefore serve as sociocultural curricular tools for passing on specific sets of knowledge to successive generations and as a means to socialize students to a given society or culture's norms and values. The concern that many curriculum scholars have with textbooks lies in the ways that explicit and often implicit messages textbooks contain have a history of reifying dominant sociocultural norms and values. This reproduction of particular understandings has a strong tendency to reproduce existing sociocultural stratifications. Generally speaking, the closer one is to a given society's norm—often expressed as a common-sense notion of what teachers, students, or curriculum look like and how they should function in a given context—the greater the likelihood that one will find that the knowledge in textbooks makes sense. Similarly, the closer one is to a dominant group's norms and values, the greater the likelihood students will see themselves represented in the content that their culture and society have deemed important enough to select for inclusion in such texts.

This curricular tendency is problematic in that it serves to remarginalize traditionally marginalized populations of society while reaffirming non-marginalized population's dominant status. In the context of the United States, this reaffirmation usually means that the farther one is from an implicit (or explicit) White, male, middle-class, English-speaking, able-bodied, Christian, heterosexual norm, the greater the chance that one's ways of knowing or being will be marginalized in textbooks. The silencing of voices, ideas, and ideals is a common theme in this literature. For example, preservice secondary teachers often can name five White male scientists yet have a great difficulty naming one female scientist other than Marie Curie and any non-White female scientist.

However, implicit sociocultural messages in textbooks are not problematic just because such messages can result in the silencing of knowledge or voices. Textbooks also contain many implicit messages about people's place in society according to a dominant paradigm. Representations of women in traditional women's roles of homemaker, mother, or caretaker with relatively little representation of women in other societal roles are but one example.

To clearly demonstrate that such messages are both present and intentional, I offer the following example of a curricular moment when implicit messages in textbooks are momentarily rendered explicit. This particular instance concerns a picture and caption in a 4th-grade social studies textbook published by a Western state that was utilized statewide. In its original printing, a caption that noted that Hispanic women often work in restaurants, hotels and motels, and housekeeping positions and that Mexican food in the state is popular. In an effort to allay public outcry over this caption, the state and publishers produced a sticker with a new caption to place over the existing offending caption that noted the positive effect Hispanics have had on the state and its economy. However, the picture above the caption of a woman in a restaurant with light skin, dark hair and eyes, wearing a server's outfit replete with a logo for a Mexican restaurant remained. While 4th graders across the state read the more positive, revised caption, they also receive state and publisher's original message about Hispanics' subservient place in society contained in the smiling picture of a Latina who looks quite happy in her literal role as server.

Thus, textbooks are institutionalized texts. Their use as curricular tools for the dissemination of knowledge includes not only their role in the reproduction and reification of dominant sociocultural norms and values, but also their location as incarnations of selected, codified, and officially sanctioned state, district, and school knowledge. However, the majority of conversations in curriculum studies about institutionalized text or the institutionalization of text pertains not to discussions of textbooks, but to how sociocultural norms, values, relationships, and knowledge in schools as institutions can be read as texts.

### Understanding Curriculum as Institutionalized Texts

In their seminal work *Understanding Curriculum*, Pinar, Reynolds, Slattery, and Taubman devote 131 pages of their textbook to "Understanding Curriculum as Institutionalized Text." This large chapter is subdivided into three overarching categories: curriculum development, curriculum and teachers, and curriculum and students, each of which is again categorized into between three and eight categories. Further complicating matters, Pinar and colleagues explicitly present the entire field of curriculum studies as a text and identify their volume as a synoptic text, a text that is designed to convey the complex conversation of the key ideas of a given field in an encyclopedia-like fashion.

Moreover, each chapter in their nearly 900-page textbook (excluding one of the most comprehensive reference lists ever compiled in the field of curriculum studies) is constructed as a text such as "Understanding Curriculum as Gender Text" or "Understanding Curriculum as Racial Text." Nearly all of these chapters also address the relationship between a given topic such as gender, race, or aesthetics and how schools function as institutions. Considered in toto, *Understanding Curriculum* suggests that the field of curriculum studies is in many ways often an examination, recapitulation, resistance, or rejection of schooling—how schools function as social institutions.

In addition to this longstanding tradition, there is also a history in curriculum studies of scholars whose work seeks to demonstrate the institutional nature of schooling. Such work tends to fall into one of two categories: scholars whose examinations of schools note the parallels between schools and other institutions and scholars who utilize previous analysis of other institutions to describe particular aspects of the daily life of schools. Peter Jackson's now-classic *Life in Classrooms* is an example of the former category. In it, he reminds the reader of the compulsory nature of schooling and its similarities to other institutions available to children, namely jails and mental institutions. Two other examples of such work are (1) George Willis's discussion of the ways that schooling reproduces social class so that working-class students become the next generation of factory workers in his

equally seminal work *Learning to Labour* and (2) Jean Anyon's depiction of how working-class students are given working-class skills while upper-class students are provided an education more geared toward managerial positions in her often-cited *Social Class and the Hidden Curriculum of Work*.

Aspects of Douglas E. Foley's work *Learning Capitalist Culture: Deep in the Heart of Tejas* and Reba N. Page's *Lower Track Classrooms: A Curricular and Cultural Perspective* are two strong examples of the latter tendency in demonstrating the institutional nature of schools. In Foley's work, Foley borrows Burroway's construct of the making-out-games factory workers play on the factory floor to get out of the monotony of their daily work lives to describe the games students play to derail classroom lessons. Page utilizes the construct of the underlife—a term Turner coined to describe the safe places, spaces, and interactions of the incarcerated that occur outside of yet do not interrupt formal, routinized interactional patterns in asylums—to describe students' classroom interactions.

In addition, with the passing of Goals 2000 and especially after the discussion surrounding and approval of the No Child Left Behind Act (NCLB) in 2001, there has been a great deal of attention focused on how federal education policy impacts local curricular decisions and outcomes. Scholars such as Linda McNeil, Deborah Meier, and Angela Valenzuela have critically questioned the ways that NCLB negatively impacts all students in general and traditionally marginalized student populations in particular.

Schools are by their very nature institutional, schools and schooling are integral to curriculum conversations, and there is great depth and breadth of research in the field that relates to schools in ways that can be interpreted as institutionalized text perspectives. Textbooks and their uses are often included in discussions of institutionalized text in general, as is the case in Michael Apple's *Teachers and Text: A Political Economy of Class and Gender Relations in Education*. The following list portrays how the field of curriculum studies approaches textbooks and their uses, yet such accounts as this one are problematic in the ways that they essentialize and marginalize perspectives and remove important nuances.

- Human interactions can be read and critically examined as texts.
- Schools are not neutral sites of dissemination, but are institutional means of enculturation to particular sets of knowledge.
- The kinds of knowledge schools provide are structured in a way that privileges some students and marginalizes others.
- Students who are privileged are likely to be part of the dominant group, and their ways of knowing serve as an implicit norm against which all students are measured, categorizations that are often based on differences from a perceived norm that are read as deficits. Sources for the construction of difference as deficit are included in the recommended readings section.
- In the United States, that norm is White, male, middle class, heterosexual, English speaking, able bodied, and Christian; the fewer of these characteristics a student has, the greater the likelihood that the student's ways of knowing and being will be undervalued.
- Schools as institutions are complex; rather than an either-or construction where people can be reduced to mutually exclusive categories, institutionalized text perspectives of curriculum have a long tradition of documenting the inherent both-and complexity of human interactions and knowledge in schools.

### Final Thoughts

In the field of curriculum studies, there is a central tendency to examine schools and schooling as text. Because all knowledge is simultaneously academic, social, and socially constructed, the knowledge schools pass on to students is inherently biased, selective, and normalizing. This result does not mean that the academic and social content students learn is not useful or valuable. Rather, it is to enunciate that the intended and unintended ways schooling operates consistently serves to reify sociocultural constructions so that differences are often cast as deficits and other or different rarely refers to students who are White, male, middle class, heterosexual, Christian, English speaking, or perceived as able bodied or able minded.

There is also a final parting complication to the consideration of institutionalized text perspectives in the field of curriculum studies. The work

described in this entry and the very volume in which it sits are located doubly as text, first as textbooks and second as particular notions about curriculum that can be read as text. As this entry illustrates, not all textbooks serve to largely reify dominant norms and values, and all texts, including this one, should be open to critical examination from the field.

## INSTRUCTIONAL DESIGN

---

Instructional design involves a range of processes created to control the learning environment. A number of theories and disciplines have influenced instructional design, particularly cognitive and behavioral psychology. Based on these premises, instructional designers control responses to instruction based upon the intentional design of the curriculum and pedagogy within a learning environment.

### History

Instructional design emerged within education as a response to the need for massive training needs during World War II. Following World War II, instructional design became a prominent force in business and industry training more so than in public education. Early instructional design was based upon B. F. Skinner's work, and training programs focused on observable behaviors. It was also influenced by the work of Ralph Tyler regarding instructional objectives to guide learning and by the work of Benjamin Bloom's taxonomy of intellectual behaviors. During the 1960s, Robert Gagne's work regarding task analysis also influenced the nature of instructional design. Elements of instructional design have been sustained over time—largely in the language of behavioral objectives. Design became more prominent in the 1980s as computer programs were designed as an alternative form of instruction. Instructional design has become more prominent since 2000 as universities and other programs have moved to more online learning.

### Theoretical Influences

Instructional design is largely influence by four theoretical foundations. First, most models of instructional design are influenced by systems theory. Products of instructional design are most often presented in instructional systems that are part of larger systems, and they support an ongoing cycle of development that includes planning, implementing, assessing, and revising. Thus, the products involve an integrated systemic plan to solve an instructional problem.

Second, instructional design is also influenced by communication theory—particularly in recent iterations heavily influenced by online learning. Instructional design models address how messages are given and received and addresses how those instructional messages may be distorted by various forms of noise within the context. Accordingly, instructional design models often focus on the need to understand the learners' prior experiences when developing instructional products.

Third, learning theory has significantly influenced instructional design models. Two learning theories in particular have made their mark in instructional design: behaviorism and cognitive

learning theory. Behavioral learning theories focus on the environment and design learning according to observable behaviors. In contrast, cognitive learning theories focus on the learner and design learning as an active, cumulative, and complex event in which the learner constructs meaning.

Fourth, instructional design is influenced by instructional theory. As such, many instructional design models attempt to prescribe specific characteristics of instruction to achieve specific aims. Examples of how instructional theory has influenced instructional design include Bloom's model of mastery learning, Gagne's theory on conditions of learning, and Keller's ARCs model of motivation.

### Difference in Scale

Instructional design is implemented according to a variety of scales. For example, a team of designers may construct a packaged reform model that can be used with a range of grade levels to teach reading. This type of model may be very prescriptive, and assessment of students and the evaluation of the program may be focused upon the explicit fidelity at which teachers implement the program. Further, universities may use instructional design as a means to develop online programs. Although the outcomes of this scale of design are not as prescriptive as the packaged reform models, the programs often maintain some degree of prescriptive nature to support disciplinary standards and other possible accreditation expectations. On a smaller scale, individual teachers or a team of teachers engage in instructional design when they deliberately plan instructional units specifically designed for their classes. In the case of the smaller scale, the planning and implementation of the designed instruction is less focused on fidelity of implementation and provides opportunities for more flexibility and interpretation.

### Common Elements Within Instructional Design Theories

A number of instructional design models have been used over time, and although each may differ from the others in terms of focus, process, and psychological assumptions, most if not all include at least four key elements. First, most if not all

instructional design models involve some level of analysis. The degree of analysis and the object of study may differ among the models, but they nevertheless analyze the nature of the context, the subject matter, and/or the nature of the learner as a key element in their process.

Second, all instructional design models address organization in some way. Most models organize according to objectives and some level of scope and sequence. Depending upon how prescriptive the model or intended product is, the level of explicit organization will differ. The higher the degree of prescription, the higher the level of organization will be evident within the model.

Third, all instructional design models address delivery of instruction. The degree of prescriptive nature regarding delivery will differ according to the models. For example, Dick and Carey's model addresses learning in terms of specific conditions of learning and prescribe steps for instruction that include such actions as gaining attention, stimulating recall, giving feedback, and assessing performance. In contrast, the Gagne, Briggs, and Wager model addresses delivery in a more experimental manner. Their model provides opportunities for experimentation and innovation.

Finally, all instructional design models include means for evaluation. Most models include both formative and summative evaluations to judge not only the performance of those being instructed, but also the validity of the instructional design. Some models such as the ADDIE model (the analyze, design, develop, implement, and evaluate model) also evaluate the use of resources and determine the impact of instruction based upon those resources. In most instructional design models, evaluation is based upon standards and the objectives formed according to those standards.

## INSTRUCTION AS A FIELD OF STUDY

---

Throughout the 20th century, educators used *teaching* and *instruction* interchangeably. Even in current literature, the distinctions are often unclear. In general terms, teaching tends to place the teacher's thinking and acting at the center of scholarly attention, whereas instruction focuses on the conditions of learning and the psychological proclivities of the learner as a resource for the teacher. Throughout the 20th century, the concept of instruction evolved within a systems approach to planning for curriculum content and teaching. Through the doctrine of behaviorism, instruction became associated with a production system for efficiency, social conditioning, and accountability. By mid-century, instruction became a technological outgrowth of scientific management and research, with emphasis not only on the teacher's actions and student achievement, but also on conditions that contribute to effective teaching and schooling. Today, instructional design is a prominent practice in education that is viewed as an efficient way to deliver certain types of training. Computer applications in education are rapidly advancing in the field of instructional design and are becoming a major influence in innovative ways of delivering instruction. As a result of the technological assumptions and imperatives for practice that are now associated with instruction, curriculum scholars have produced a body of criticism to challenge the dominant technological view that influences both teaching scholarship and instructional design.

### History of the Field of Instruction

Toward the end of the 19th century, there emerged early influences that signaled a field of instruction. The eminent German psychologist, Johann Friedrich Herbart, was the first educational writer to put an emphasis on instruction as a process that focused on the pupil's experience. This focus required the

teacher to attend to the child's previous knowledge and interest. With this psychology, the teacher was told to follow a systematic procedural guide known as the five formal steps of teaching and learning. The steps were articulated as follows: (1) preparation, bringing the pupil's previous learning experiences to his or her attention; (2) presentation, giving new information; (3) association, showing the relationship between the new and the old information; (4) generalization, making up rules or general principles that express the meaning of the lesson; and (5) application, giving the general principles meaning by using them in a practical way or by deriving specific examples. Many Americans went to Germany to study Herbart's ideas during the final decades of the 19th century. The American Herbartians formed a club that became the National Herbart Society. In a few years, the National Herbart Society's name was changed to the National Society for the Scientific Study of Education. Their reform movement was relatively short lived; however, their influence helped to undermine the dominant theory related to classical mental discipline (e.g., faculty psychology). Herbartianism functioned as a transitional theory toward child centeredness, and later, the theory of faculty psychology fell victim to a triumphant experimental science of psychology.

The turn of the 20th century brought scientific promises in experimentation and measurement that shaped psychological thinkers such as G. Stanley Hall of Johns Hopkins University, Charles Ridd of the University of Chicago, and Edward Thorndike of Columbia University. Thorndike, for instance, claimed that if something exists, it exists in a given amount and as such, is capable of being measured. He reflected the belief that scientific knowledge of stimulus-response behavioral patterns would enable educators to alter human behavior. He described education as a form of human engineering that would profit by measurements of human nature and achievement. From the work of Thorndike and other experimental psychologists emerged the push for a science of instruction and the beginnings of instruction as a production system.

### Instruction as a Production System

The origin of the notion of instruction as a production system can be traced to efforts during the

early decades of the 20th century to apply industrial scientific management to education. In later years, instruction as a production system was related to the doctrine of behaviorism, systems analysis, and accountability. By mid century, with focus on accountability, evaluation became a central practice in the field of instruction. Ralph W. Tyler, perhaps one of the most influential educators in evaluation, served on a number of bodies that influenced policy and set guidelines for the expenditure of government funds. His work helped to codify educational evaluation as it pertained to aligning measurement and testing with specific educational purposes. By this time, it was customary for scholars and practitioners to consider curriculum as a design problem. The well-known Tyler Rationale was articulated in *Basic Principles of Curriculum and Instruction* as the way to consolidate parameters for analysis of the internal components of curriculum construction—goals, implementation, and evaluation. Curriculum planners were guided to consider a curriculum program that consisted of purposes, learning experiences, organization, and evaluation. Program evaluation, then, was intended to determine the effective aspects of the program and to revise the areas that were not effective. In his book, Tyler described learning as taking place through the action of the student, not what the teacher does.

As program design became a common activity, instruction served as a technological outgrowth of scientific research. In 1963, the first *Handbook of Research on Teaching* summarized major breakthroughs, and in subsequent decades, handbooks and related volumes summarized research on teaching for scholars and practitioners. Although research focused primarily on the teacher's actions and student achievement, there was also a strong emphasis on conditions that contribute to effective teaching and effective schools as instrumental content for instruction. The intent was to build a massive body of empirical data on instructional content and process that would build a scientific basis for instruction.

Scholars such as Jerome Bruner began to call for a theory of instruction that could be refined constantly and would be used to explain, predict, and control instruction and teaching. His *Toward a Theory of Instruction* described a popular course of study that illustrated psychological theories

that Bruner posited would lead to a theory that could guide pedagogy. His theories of cognition were used to select and build a variety of materials about tool making, social organizations, and child rearing. The process was one of studying certain characteristics of people and using these characteristics to select aspects of the world of others that are brought into the school. Learning theory was used to determine sequence and the responsiveness of the fabricated environment. Motivational theory was used to construct the interfaces and information system.

Educational psychologists and instructional designers began to consider cognitive theory, not only as something that explains what happens in the head of the student, but also as a way of fabricating the scenes or settings within which education occurs. By considering psychological theories, whether learning theory, motivational theory, or cognitive theory, not as the psychologist does (i.e., as valid ways of explaining mental processes within students), but as powerful tools for designing educational environments, instruction would have a solid foundation. As such, psychological theories were seen as world building tools and as tools for understanding students.

Under the concept of instruction as a production system, curriculum was conceived as a separate process from instructional design, described as a structured series of learning outcomes. The planning process became curriculum development, and the results were used as input into the instructional system. Educational objectives became the dominant way in which learning outcomes were expressed and the evaluation aspect of instruction involved a comparison of actual learning outcomes with the intended learning outcomes. The teacher was conceived as one who plays a role in an instructional scenario. Thus, instruction, as a production system, became something that was delivered by a teacher or instructional designer. Today, this general view of instruction remains in various design models.

### Instructional Design and Technology

Instructional design, a major practice in the field of instruction, became significant during World War II when the U.S. War Department needed to train military personnel and employees rapidly in

war-related industries for complex responsibilities. Drawing from behavioral psychologists, the initiatives paralleled the efforts of curricularists and evaluators in education. Tasks were differentiated into subtasks, and each was treated as a separate objective or learning goal. Training was designed so that each learner could achieve mastery through repetition and feedback. Learners were rewarded for correct performance or were remediated if needed. Many of the concepts used in military training remain in current educational curriculum development and instructional design language (e.g., objectives, task analysis, instructional strategies, formative evaluation, etc.).

As instructional design became a significant practice in education, the concept of instructional technology was used to describe many of the aspects of a systems approach. Audio and visual instruction was seen as an efficient way to deliver certain types of training, which included highly structured manuals, instructional films, and standardized tests. During the latter part of the 20th century individualized instruction and learning became a goal in educational discourses. Educators advocated it as a way to accommodate to individual differences in learners. Programmed instruction using teaching machines gave way to programmed texts and other applications of behaviorism. As the individualized instruction movement declined, it was replaced by computer-based instruction, and with the advent of affordable personal computers, instructional design and technology have become major practices in education.

Today computer applications in education are rapidly advancing in the field of instruction. A list of five types of computer-based instructional programs gives a glimpse of the array of educative activities related to technology. They are as follows: tutorials, drill, simulations, games, and tests. The term electronic learning (or e-learning) is now coined to indicate a type of education where the medium of instruction is computer technology. E-learning is known as a planned teaching or learning experience that uses a wide range of technologies, primarily Internet or computer-based programs, to reach learners. In some instances, there is no face-to-face interaction with an instructor. In schools and colleges, e-learning is used to refer to a specific modality for attending a course or study program. Students may not necessarily attend

face-to-face instructors on campus, but may study exclusively online. Educators who design and/or deliver online materials and courses are expected to be highly skilled in instructional design, especially in a content area and computer and Internet use. In addition, they are expected to work well with the special needs of e-learners. Online courses are rapidly increasing in educational institutions.

### Criticisms

As a result of the technological assumptions and imperatives for practice that are associated with the concept *instruction*, many scholars in the field of curriculum studies prefer to use *teaching* rather than instruction and are troubled by the dominant view. William Schubert, for instance, suggests that teaching is a more comprehensive term that relates to the artistry of everyday intuition and decision making by those who have the experience to be connoisseurs of their craft. Herbert Kohl describes teaching as a craft or as a skilled know-how that is acquired more through apprentice-like involvement with mentors than by following rules derived from scientific research or technological models. Elliot Eisner identifies various senses in which teaching is an art. It can be performed with such skill and grace that it can be regarded as aesthetic. Like performance in painting or music, teaching involves the making of judgments based on the perceptions of qualities that unfold in the course of action. It is best carried on without the domination of prescriptions or routines because the teacher must be able to respond to the unpredictable. In addition, teaching involves the creation of ends in the process rather than prior to it through discrete prespecifications.

Michael Apple is critical of the number of control systems that are embodied in structures rather than people. Technical control, like that of instructional design, is one of these. Apple points to the integration of management systems, reductive behaviorally based instructional design, prespecified teaching competencies, and pre- and posttesting as examples of control being embedded in the education instruments of production. Instead of control appearing to flow from management to teacher, it is built into the more impersonal forms of instructional teaching materials. Technical control is encoded into the very basis of the curricular

form itself. Thus, the “teacher-proof” materials determine what is taught and how sequenced lessons decide the form and timing of assessment and establish the pace of teaching. Apple is especially concerned that these materials are often developed at great expense by entrepreneurs outside the school.

C. A. Bowers observes that, in effect, a 21st-century view of knowledge involves the personal computer as a powerful and legitimate tool of the teacher and students. However, insofar as computers embody the conceptual framework (and the ideology) of the experts who devise them, the technology itself can be viewed as reproducing a specific ideological orientation. Further, Bowers suggests that this ideology is based on fundamental misconceptions regarding the nature of the individual, the nature of knowing (including intelligence), and more specifically, how individual empowerment relates to social progress. More generally, he is concerned that the metaphor of an information age that he regards as the most recent expression of this ideological orientation, functions to hide the moral and spiritual character of the ecological and social crisis of the 21st century, a concern shared by other curriculum studies scholars.

Daniel Tanner and Laurel Tanner are troubled by the newer instructional technology and the growing trend toward standardized achievement testing that have given impetus to conceiving curriculum in terms of test results. With schools and teachers being evaluated according to student scores on standardized tests, there has been an increasing tendency for teachers to teach to the test. Hence, the test not only provides the quantitative data on the outcomes of instruction, but also exerts a powerful influence on instructional processes and very largely determines the curriculum. In effect, the curriculum is seen as the quantitatively measured outcomes of instruction. Such a conception of curriculum reduces the schooling process itself to a technological system of production.

## INTEGRATION OF SCHOOLS

---

The concept of the integration of schools has influenced the field of curriculum studies by enhancing the understanding of how schools operate, providing an undergirding for multiculturalism, informing the study of tracking and ability grouping, and serving as a foundation for professional development for teachers working with diverse youth. The integration of schools refers to the process by which desegregated schools replace an ethnocentric curriculum with one that incorporates previously marginalized voices and perspectives. To prevent the conflation of these terms, integration is first distinguished from desegregation, and then theoretical perspectives of integration, curriculum, multiculturalism, and tracking are discussed.

### Integration Versus Desegregation

In 1954, the U.S. Supreme Court ruled in *Brown v. Board of Education* that educational facilities

segregated on the basis of race were unequal and called for separate school systems to be terminated with all deliberate speed. The desegregation of elementary and secondary schools transformed the space within which students were legally permitted to attend school, signifying a change in the ecological conditions of schools. Although desegregation is a necessary prerequisite to remedy school segregation that was deemed illegal in *Brown*, it is insufficient to achieve integration.

Gordon Allport's intergroup contact theory is central to the idea of integration and has been shown to reduce prejudices between racial and ethnic groups. In addition to desegregation, Allport's theory suggests that the following four conditions are necessary to achieve integration and reduce intergroup prejudices:

1. equal status between all involved groups,
2. involved groups work toward a common goal,
3. cooperation is emphasized while competition is de-emphasized, and
4. adults and authority figures offer their full support.

The four conditions suggested by Allport's theory facilitate the reduction of prejudices between racial and ethnic groups. Integrated schools experience these four conditions in addition to desegregation, while desegregated schools simply permit members of different racial and ethnic groups to attend the same school.

### Integrated Curriculum and Multiculturalism

From a sociological perspective, curriculum traditionally has been viewed as a tool with which to socialize groups, particularly, to socialize the Other. Specifically, curricula have served to assimilate subordinate groups to the dominant group's norms, values, culture, and language. Integrated schools not only challenge ethnocentric curricula used to socialize the Other, but also incorporate the voices and alternate perspectives of previously marginalized groups. Following the same four conditions posited by Allport, an integrated curriculum views multiple perspectives equally, encourages cooperative learning, is oriented toward a common goal, and authority figures including parents, teachers,

principals, and upper-level administrators fully support the curriculum design.

Integrating multiple perspectives into the curriculum should not simply be additive or supplementary to the previously established curriculum. In higher education, this supplementary structure is seen in the addition of women's studies and ethnic studies, which do begin to give voice to those historically marginalized, but exist separately from mainstream course offerings and requirements. In elementary and secondary schooling, this phenomenon can occur when the curriculum includes culturally specific events or celebrations such as Black History Month without integrating the voices and perspectives of marginalized groups into the mainstream, everyday curriculum. In this sense, students are exposed to a superficial understanding of these perspectives, their importance is significantly reduced, and such curriculum designs perpetuate ethnocentrism. Much like desegregation is necessary but insufficient to create equitable educational opportunities, multiculturalism that is simply conceptualized but not carried out is insufficient as well. To this effect, multicultural curriculum that is improperly developed or implemented works against the integration of schools. Multicultural efforts should simultaneously challenge existing curriculums and the power structures they represent while offering alternative perspectives from what has traditionally been considered the norm. Integrated multicultural efforts are built into the curriculum and maintained in the course offerings, the design of specific courses, and in the course materials used.

Although desegregated schools feature tracking mechanisms that reassemble students along race, ethnic, class, culture, and social lines, integrated schools attempt to provide equitable learning opportunities regardless of one's ascriptive characteristics or status in society. The curriculum found in affluent, predominantly White schools is typically oriented toward preparing students for college, in contrast to less affluent, high-minority schools that typically offer a curriculum that is vocationally oriented.

### Future Considerations

As the United States is becoming increasingly diverse, differences between and within subgroups

of racial and ethnic categories are becoming increasingly apparent. Integrated schools will need to adapt to the changing demographics of the students they serve, as well as the nation as a whole, while also acknowledging that not all racial and ethnic groups are homogeneous. At the same time, the opportunities for integrated schools to exist may decrease, particularly given the high rates of de facto segregation and the legal parameters from within which student assignments are made, which collectively threaten the chances of integrated schools to exist. Although this definition has focused primarily on integration along racial and ethnic lines, it can also be expanded to include other groups that have historically been marginalized, such as by gender, culture, and class.

## INTELLIGENCE TESTS

---

Intelligence testing is the process of measuring cognitive ability using standardized measures and scales. The use of intelligence testing for education purposes, including curriculum differentiation, is controversial. This entry discusses the history and criticisms of intelligence testing, along with the role of intelligence testing in curriculum differentiation.

### History

In 1905, Alfred Binet and his medical student, Theodore Simon, developed a diagnostic method for distinguishing abnormal from normal boys in his Sorbonne laboratory and the Perray-Vaucluse asylum. During the late 1910s, Henry Goddard translated the *Binet-Simon Scale* and administered it to his young Vineland Training School charges and about 2,000 children in local New Jersey schools. Goddard wanted all children to be examined, individual by individual, claiming that 2% of school students were feebleminded or mentally defective. Like Binet, he defined low-grade intelligence as arrested mental development with classifications of idiot, imbecile, and moron and recommended segregation into ungraded, special classes and surgical sterilization for these students. Over 25,000 copies of Goddard's translation were distributed across the United States by the time Lewis Terman's *Stanford Revision of the Binet-Simon Scale* was published in 1916. By 1920, the Bineting of individuals had slowed considerably as the *Army Alpha Scale* was transformed into the *National Intelligence Test*; the new group tests enabled a single psychologist to examine large masses of students simultaneously. Although Binet found intelligence to be variable, ranging in levels of comprehension, judgment, reasoning, and invention, this finding was contentious—for other psychologists intelligence meant mental adaptability to new problems and was fixed as a trait. Intelligence tests were the most utilized instrument in psychology through the 1920s; about 300 cities in the United States and Canada were using intelligence tests for ability grouping by 1930. Albeit with resistance, during the 1910s and 1920s, school access was granted to university researchers to measure students' literacies, physicians to inspect students' bodies, and psychologists to examine students' minds.

### Criticisms

Criticisms came from physicians and psychiatrists claiming that psychologists transgressed their jurisdiction into therapeutics. Populist groups countered that intelligence examinations were implicated in the medicalization of schools. University students sarcastically dismissed claims that intelligence tests provided views into the

inner workings of their heads. In the early 1920s, academics such as John Dewey critiqued the tests as inequalitarian, while journalists such as Grace Adams skewered the testers as pseudo-scientists. In the mid 1920s, fueled by notable reports, including Terman's *Measurement of Intelligence* (1916) and Carl Brigham's *Study of American Intelligence* (1923), African American intellectuals, such as W. E. B. Du Bois, exposed premises of eugenics and challenged the validity of IQ tests by identifying cultural biases, factoring economic conditions and educational opportunity into findings. By the end of the decade, students grew tired from the response burden, and administrators grew wary. In 1932, the National Education Association (NEA) announced that the tests were dethroned and in 1933 the U.S. Senate moved to regulate testing as a basis for classifying, grading, or segregating school students. The desegregation decision for *Brown v. Board of Education* (1954) relied on a social science statement reiterating the variabilities and contingencies of intelligence test results. However, intelligence testing only temporarily slowed or was superseded by achievement tests and the courts were reluctant to intervene in ability grouping practices, despite calls for moratoria by the Association of Black Psychologists and NEA in the 1960s and intense legal challenges in the 1970s and 1980s.

### Curriculum Differentiation

Indeed, few educational practices are more controversial than intelligence testing and the differentiation of curriculum. In the 1910s, scientific curriculum makers, such as Franklin Bobbitt, combined efforts with intelligence testers to differentiate and individualize courses of study. By the late 1920s, teachers' professional judgment was nearly fully displaced by psychological knowledge and tests; grouping, tracking, and differentiation decisions were increasingly made in administrative offices. Through the 1950s, the Winnetka plan and others provided models for adjusting curriculum to ability groups and individual differences or raising and lowering standards. To what degree does curriculum differentiated by content, pace, and quantity unequally distribute achievement and opportunity? In 1979, the Circuit Court decision for *Larry P. v. Wilson Riles* (1979) challenged the disproportionate number of African American

students classified in special classes, specifically arguing that San Francisco Unified School District's educable mentally retarded curriculum was a dead end, de-emphasized academic skills, and stigmatized children improperly classified. The findings and decision were similar for *People Who Care v. Rockford Board of Education* (1997) as *The Bell Curve* refueled controversy and the American Psychological Association issued a statement guarding against rampant politicization of intelligence testing findings and practices.

## INTELLIGENT DESIGN

---

*See* Creationism in Curriculum: Case Law

---

## INTENDED CURRICULUM

---

The intended curriculum is the overt curriculum that is acknowledged in policy statements as that which schools or other educational institutions or arrangements set out to accomplish. Sometimes the intended curriculum is contrasted with the hidden curriculum (that which is learned from the structural organization of the schooling institution and the society in which it is embedded), the taught curriculum (teachers' interpretations of the intentions set forth in policy or their intentional substitutions for that which is intended), the null

curriculum (that which is not emphasized), the tested curriculum, and the learned curriculum.

Normally, it is framed within a conceptualization derived from the writings of Ralph Tyler, known as the Tyler Rationale, which was originally developed as a set of principles to guide curriculum and instruction. These principles are based on selection from a combination of emphases: philosophical assumptions, psychological models of learning, perceived interests of learners and conceptions of their individual needs, sociopolitical and economic contexts and mandates, and conceptions from experts from the several disciplines of knowledge on the nature of subject matter to be learned.

Intended curriculum is often stated in general statements to allow for situational interpretation and adaptation, though sometimes it is given precise behavioral specification, and in less frequent instances, it is begun with a general sense of direction statement from which situational curriculum will evolve or provocative or imaginative materials that elicit expressive consequences.

Procedural criteria for developing intended curriculum policy statements include representation, clarity, feasibility, and defensibility. The ends of such inquiry emphasize one or more of the following: socialization, achievement, personal growth, and social change.

Intended content may, therefore, take the form of subject matter, specified learning activities, or learning experiences, and any of these may be analyzed by focusing on sources of derivation: societal needs, test of survival, structure of the disciplines, utility, publisher (of instructional materials or textbooks) decision, political pressure, learner interest, democratic values, among others.

Statements of intended curriculum often detail aspects of organization. For example, curriculum guides are often vertical (depicting topics across different subject matter pursued as the same time) and horizontal (depicting increased exposure to topics over the years). Regarding the latter, when the same topics are revisited with increased perspective, the phenomenon is referred to as the spiral curriculum, drawn from the work of Jerome Bruner in the 1960s.

Intended curriculum statements also provide other dimensions of scope (breadth beyond separate subject matters to include combined subjects,

projects or core curricula that draw upon diverse subjects, and integration of subjects to facilitate personal and social development). Similarly, sequence is often treated as broader than a yearly listing of topics; it might accept or critique presentation in textbooks or other instructional materials, educator preference, student preference, structure of the discipline and concomitant notions of prerequisite knowledge, hierarchies of learning (e.g., simple to complex, facts to concepts, principles, and values), developmental appropriateness according to different theories of human development.

Another dimension of intended curriculum is specification of learning environment, for example, departmentalization, self-contained classroom; nongraded classrooms, open classrooms, tutorials, computer-based instruction, community-based learning, and a range of other options in school or outside of school. Such environments may be analyzed relative to several dimensions: physical, material (instructional), interpersonal, institutional, and psychosocial.

A final dimension of statements of intended curriculum is evaluation. This relates to a vast or narrow range of evidence (e.g., through testing, observation, interviews, and products produced) about the extent to which intended purposes are met, the unintended consequences of the curricular process employed, and development of plans to revise the intended curriculum to more fully meet needs and interests of learners.

## INTERESTS OF STUDENTS AND THE CONCEPTION OF NEEDS

Attending to the interests of students and the conception of needs proved to be one of the more important curricular design issues of the early-to-mid 20th century. In what became a progressive education emblem, the now forgotten phrase “attending to the interests of students” represented one of the fundamental principles of progressive education. More sophisticated definitions of progressive education added the phrase, “meeting the needs of students,” in what would historically prove to become a factor for determining the scope of the curriculum. Although designing curriculum to attend to the interests and needs of students may seem a commonsensical belief and simple concern, the topic proved highly controversial within the Progressive Education Association (PEA) and continues to prove problematic for designing any student-centered curriculum.

The importance of students’ interests and creative expression helped to form the PEA and to articulate a type of education separate from the institutional, factory-oriented conception of schooling. Focusing the curriculum on student interests was popularized in the 1918 article, “The Project Method,” by William H. Kilpatrick. Students’ interests could become the center of the curriculum; however, for Kilpatrick a hearty, purposeful act was a requirement for this curricular-instructional focus. Yet many educators were concerned that such a curriculum would lead to any interest becoming a legitimate part of the curriculum. Kilpatrick’s requirement of purposeful activity introduced a filter that ruled out what some educators would consider a childish whim of students with little educational purpose.

During the 1930s to 1940s, a number of PEA members turned their attention to the sociological and psychological determination of adolescent needs rather than student interests as a way to configure the curriculum. These developmental needs, based upon the emerging conception of adolescence, came to be seen as a balance of student interests. The concept of needs expanded to include personal and social needs and in many ways, received its most sophisticated treatment in the PEA’s Eight Year Study and the work of the Commission on the Secondary School. This group,

led by V. T. Thayer, issued a series of curriculum reports that configured the middle and secondary school curriculum around a framework of student needs: personal, immediate personal-social relationships, social-civic relationships, and economic relationships. These themes served to identify worthy interests and needs for selecting and organizing appropriate learning experiences. The Commission on the Secondary School, however, emphasized personal and social needs more than academic content in designing curriculum, proving disconcerting for some educators.

Although the PEA believed its recognition of personal and social needs reconciled the unfocused aspect of centering the curriculum on student interests, Boyd Bode expanded further the conception of needs by distinguishing between real needs and felt needs (e.g., whims) and criticized the PEA and Eight Year Study for their use of needs as the organizing principle for curriculum design. Determining student needs, which ultimately proved an act of determining what students lacked and what they ought to know, was a form of indoctrination and the imposition of values. Bode reconciled the issue of the conception of needs by maintaining that the defining principle for curriculum construction was not defining needs, but instead determining a social vision and philosophy of school in society. Rather than viewing what students lacked—an absence of knowledge—Bode reconceived the conception of needs as an act of establishing a social philosophy.

During the years following the Eight Year Study, proponents of a life-adjustment education movement drew upon the developmental needs-adolescent tasks research and reconfigured student interests and needs to focus primarily upon personal interests and vocational roles. Life-adjustment programs became easy targets for criticism, and the 1950s’ attacks on student-centered curriculum increased as attention to the conception of needs decreased. Currently, student needs, if recognized, typically are viewed as lacks—student inabilities and minimum competencies related to the basics (of academic performance) and to employment and citizenship.

## INTERNATIONAL ASSOCIATION FOR THE ADVANCEMENT OF CURRICULUM STUDIES

---

The International Association for the Advancement of Curriculum Studies (IAACS) was established in 2001 to support a worldwide, but not uniform, field of curriculum studies. IAACS recognizes that curriculum occurs within national borders and that often curriculum inquiry is constrained by government, culture, and tradition. However, IAACS recognizes that those borders have become very permeable and that the advancement of the field of curriculum studies acknowledges the importance to the field of opening conversations through and across those borders. The mission of the organization is to promote scholarly conversations concerning the content, context, and process of education in specific localities.

The association began as a Committee of 100 and developed from the Committee of 100 that arose out of the 2000 Louisiana State University Conference on the Internationalization of Curriculum Studies, organized by William Pinar, William Doll, Donna Trueit, and Hongyu Wang.

The governing structure of IAACS consists of a President, Vice President, Secretary, and Treasurer. At present (2007–2010) the association officers are President, Zhang Hua (China); Vice President, Terry Carson (Canada); Treasurer, Elizabeth Macedo (Brazil); and Secretary, Wayne Hugo (South Africa). The general assembly of the association consists at present of members from 33 nations and represents six continents. There is a third group of permanent, nonelected members who are responsible for organizing and maintaining the association's Web site (Jacques Daignault—IAACS site

Webmaster; Laurent Duschene—IAACS site technician; and Renée Fountain—IAACS site coordinator. Neil Gough (Deakin University, Australia) edits the online publication of the IAACS Journal, *Transnational Curriculum Inquiry*.

The association sponsors an international conference every 3 years. Beginning at the founding conference at Louisiana State University in 2000, regular conferences were held in Shanghai, China (2003); Tampere, Finland (2006); and Cape Town, South Africa (2009); future conferences will be held in South America (2012) and North America (2015). The conference will return to Asia in 2018.

## INTERNATIONAL ENCYCLOPEDIA OF CURRICULUM

---

The *International Encyclopedia of Curriculum*, published in 1991, is a major, one-volume reference work of 1064 pages that was edited by Arie Lewy. It was derived from his work as editor of the curriculum articles of the *International Encyclopedia of Education*, a 10-volume set edited by Torsten Husen and T. Neville Postlethwaite in 1985, with a supplement published in 1989. Several encyclopedias on different topics were

derived from the original volume and supplement. Curriculum is one of these topics.

The encyclopedia is distinctive in the diversity of international authors and topics germane to many different parts of the world. It is introduced by John Goodlad, who writes of curriculum as a domain of scholarly inquiry. The encyclopedia is divided into 13 sections: (1) conceptual framework, (2) curriculum approaches and methods, (3) curriculum processes, (4) curriculum evaluation, (5) language arts, (6) foreign language studies, (7) humanities curricula, (8) arts curricula, (9) social studies, (10) mathematics education, (11) science education programs, (12) physical education, and (13) international curriculum associations and journals.

Although several subtopics and individual articles of the *International Encyclopedia of Curriculum* offer perspectives on what is not considered to be curriculum studies today, the volume gives a valuable international perspective on what constituted curriculum studies at the beginning of the 1990s.

## **INTERNATIONAL HANDBOOK OF CURRICULUM RESEARCH**

---

The *International Handbook of Curriculum Research*, a collection of essays edited by William

F. Pinar, contributed to expanding international perspectives in the areas of curriculum studies and research. The text's publication in 2003 followed the establishment in 2001 of the International Association for the Advancement of Curriculum Studies (IAACS). According to Pinar, both of these can be seen as companion events. The text assisted in establishing that curriculum studies, far from being exclusively an U.S. field, has an international context. It demonstrated that there was a worldwide field of curriculum studies. This volume of essays was the first book to emphasize and analyze curriculum studies internationally. This focus was a major contribution and an extension of internationalization to the field of curriculum studies. The attention to international curriculum studies was a direction initially discussed in *Understanding Curriculum Studies* (1995).

The *International Handbook of Curriculum Research* is comprised of 38 chapters in which curriculum research in 29 nations is discussed. Far from being an attempt to coalesce curriculum research in many nations into one common curriculum studies field, the effort of this text was to first place international curriculum research within the historical, political, socioeconomic, environmental, and cultural phenomenon of globalization and second to begin complicated curriculum conversations crossing national borders.

The first section of the text, "Four Essays of Introduction," elaborates on in-depth conceptualizations of globalization and its consequences that move beyond simple economic or trade studies for the 21st century. The authors included are David Geoffrey Smith, Noel Gough, Claudia Matus, Cameron McCarthy, and Norman Overly.

The second and main section of the handbook, "Thirty-Four Essays on Curriculum Studies in 28 Nations," highlights scholars' discussions of curriculum work in Argentina (Silvina Feeney, Flavia Terigi, Marino Palamidessi, and Daniel Feldman), Australia (Bill Green), Botswana (Sid N. Pandey and Fazalar R. Moorad), Brazil (Antonio Flavio, Barbosa Moreira, Alice Casimiro Lopes, Elizabeth Fernandes de Macedo, and Silvia Elizabeth Moraes), Canada (Cynthia Chambers), China (Hua Zhang and Qiquan Zhong), Hong Kong (Edmond Hau-Fai Law), Estonia (Urve Laanemets), Finland (Tero Autio), France (Denise Egea-Kuehne), Ireland (Kevin Williams and Gerry

McNamara), Israel (Naama Sabar and Yehoshua Mathias), Italy (M. Vicentini), Japan (Miho Hashimoto, Tadahiko Abiko, and Shigeru Asanuma), Mexico (Angel Daz Barriga and Frida Diaz Barriga), Namibia (Jonathan Jensen), Zimbabwe (Jonathan Jensen), the Netherlands (Willem Wardekker, Monique Volman, and Jan Terwel), New Zealand (Peter Roberts), Norway (Bjørn B. Gundem, Berit Karseth, and Kristin Sivesind), Romania (Nicolae Sacalis), South Korea (Yonghwan Lee), Philippines, Malaysia, Thailand (F. D. Rivera), Sweden (Ulla Johansson), Taiwan (Jenq-Jye Hwang and Chia-Yu Chang), Turkey (F. Dilek Gözütok), the United Kingdom (David Hamilton and Gaby Weiner), and the United States (Craig Kridel, Vicky Newman, and Patrick Slattery). The writers of the 34 essays discuss the historical dimensions and the state of curriculum research in their various countries. The text not only allows the readers to concentrate on curriculum issues within their own individual regional or national field, but also allows curriculum scholars and students to reflect and research on the field worldwide.

Pinar in the conclusion to the introduction to the handbook, titled "Next Steps," determines that several issues become evident after reading the work done in curriculum internationally. First, curriculum work most often centers on an individual's nation or region. Second, work in curriculum in most nations concentrates on reform in the areas determined by governmental policy. Third, despite the fact that curriculum work can be driven by governmental policy, work in curriculum internationally has a critical questioning of the work and language of school reform. Finally, much of the work done in curriculum already has an international component and is already concerned with international issues, particularly the appropriation of the scholarly work of other nations to a scholar's own nation and region, of course, not without an awareness of that appropriation.

The scholarly work in curriculum studies is given a showcase in this volume. The movement toward a complicated international conversation concerning curriculum studies and the research connected to it are enhanced in the *International Handbook on Curriculum Research*.

## INTERNATIONAL PERSPECTIVES

---

Despite the Western origins of the term *curriculum* (from the Latin, *currere* meaning "to run the course"), the basic concept behind this meaning has been broadly adopted across national boundaries and cultures. Most countries of the world have identified a period of time when it is compulsory for young people to attend school. At the heart of school attendance is the curriculum: a program of study or learning that has been designed to meet the needs of young people themselves as well as the communities in which they live. Yet the content and structure of the curriculum is not uniform across countries. Local priorities and issues, local cultures, and local pressures come together to influence the form that the curriculum takes. This emphasis on the local can be at odds with global influences that can exert pressures on the curriculum for uniformity and standardization. This tension between the local and the global is often influenced by the ways in which the school curriculum has been constructed historically (especially in countries that have come under colonial domination) and culturally (especially where cultural traditions have valued education and the preparation of young people for their future roles in society). From an international perspective, therefore, the curriculum shares similarities across the globe in

terms of its basic purposes but takes on different forms to reflect local conditions. This means that student mobility can be limited since it can be expected that curriculum differences rather than similarities will predominate. This is not just a technical issue about curriculum content: It has more significant implications.

One important implication is that access to knowledge and skills across the globe is not the same for all students, just as it is not the same within most societies. On a global scale, however, these inequalities can be striking. In advanced industrial societies there may be debates about bandwidth and the size of computer memory to support curriculum innovation, but in other less privileged societies there may not even be electricity to support the most basic of household needs. The level of literacy is of concern in all societies but for some young people in developing countries, especially girls, attaining literacy may remain an unrealized dream. Issues of core curriculum, or what should be the essential components of the curriculum, are likely to always be debated and contested. Yet in some parts of the developing world the issue is not just an academic or even a political issue. In the case of a subject like health education, for example, having access to knowledge of health related practices may well be a matter of life and death. In such a context, it can be argued that health education cannot be debated: It must be mandated.

From an international perspective, therefore, diversity and variability characterize the school curriculum. What is important in one country and culture may not be significant in another and what one country may be able to afford in terms of curriculum provision may not be affordable in another. The equity implications of this are clear at the international level and this provides the curriculum with an important social function. The remainder of this entry provides an international perspective on the school curriculum, highlighting its diversity and social function while also identifying important equity issues that arise in specific contexts.

### International Practices

Valued knowledge is at the heart of any curriculum, but the value placed on knowledge varies across countries, although it does not vary absolutely. For

example, countries with an advanced industrial or postindustrial economy are likely to highlight the importance of mathematics and science as well as literacy in both mother tongue and possibly also a second language. These are the school subjects that are seen to be the most likely contributors to economic growth. Such a curriculum emphasis does not have geographical boundaries. It will be found in countries such as the United States and Australia as well as in China and Thailand and throughout most of Europe. There will be some variations to this kind of curriculum in different locations, but where economies are moving in a direction that requires scientific knowledge and skills, so too will the school curriculum.

Given the importance of such an economic impetus, not all countries will embrace such a curriculum. In Nepal or Bhutan, for example, where economies are more at the subsistence level, the focus of part of the curriculum is likely to be on agricultural and health issues as well as basic literacy skills since it is such content that can contribute to both personal and social development. In addition, universal access to primary education cannot be assumed in all countries, so adult education programs will continue to promote similar curriculum emphases to try to ensure as wide a coverage as possible. The social function of this kind of curriculum is exactly the same as that in postindustrial economies: to prepare young people for future participation in their societies. Yet the content will differ markedly based on the development of local economies and their trajectories for future growth.

Although curriculum content and emphases differ across countries based on the economic needs of those countries, there is at least one area of similarity: All countries, in one way or the other, will focus on the social education of young people through school subjects such as history, geography, or civics. These subjects might be best understood as the socialization subjects that seek to incorporate young people into the national stories of their country. There is often much contestation about these subjects both within and across countries. For example, the way in which Japanese textbooks portray Japan's role in World War II is often of great concern to citizens in China and Korea where deep resentment of Japanese intervention still remains. In the same way, there are different views of the history of the United States

or Australia from within those countries and this often leads to criticisms of history textbooks when they do not portray a full range of views of the past. In the countries of Eastern Europe there has been a considerable emphasis on democratic civics education since 1989 to support the new democracies as they develop more market-oriented economies and democratic electoral politics. Such emphases simply replace an older civics that championed the virtues of the previous communist states in Eastern Europe. The use of curriculum for socialization purposes, therefore, is a political tool used by all governments. Its orientation is determined by current power elites. The pervasiveness of these socialization practices mediated through the school curriculum is best understood when viewed in an international perspective across nation states.

If there is diversity in the content of the curriculum viewed across different countries, there is a similar diversity when it comes to the promotion of specific values. Some indication of this diversity has already been shown with reference to those school subjects a major purpose of which is the socialization of young people. Yet in addition to socialization by school subjects, there is also socialization to local or national value sets. Of course, these value sets can differ from country to country and can often be in conflict with one another. Values underpinning the school curriculum can be a potent force for national cohesion and sometimes international tension. The same values can achieve both outcomes.

In China, for example, all students take a subject called political education that is designed to develop allegiance to the Chinese Communist Party. In the United States, on the other hand, all students will undertake a civics-oriented subject, defined differently by different state jurisdictions, and this will seek to develop civic literacy about the institutions of a liberal democracy and an ongoing commitment to the values underlying such a democracy. In a more recent development, schools in England and Wales have been asked to include British values in their citizenship education curricula in order to develop a more socially cohesive citizenry in an increasingly multicultural British society. In all of these cases, secular values are promoted as are loyalties to a particular nation-state and indeed a way of life. The role of

the school curriculum in promoting these secular values is similar across these three countries although the specific values are not.

The school curriculum, however, is not only used to promote secular values. It is also used to support decidedly religious values, sometimes portrayed as faith-based values. This is true in a country like Pakistan that, as an Islamic society, includes religious practices and values consistent with that faith throughout its school curricula. The Republic of Ireland, as a predominantly Roman Catholic country, includes Christian values as part of its school curriculum. In Thailand, the influence of Buddhism on the school curriculum is notable as it is in Bhutan. Even within countries that are avowedly secular, such as Australia and the United States, faith-based schools have been established with a values curriculum representing whatever particular religious group sponsors the school. In Australia, for example, this means that the state that provides funding for such schools will support Christian, both Protestant and Catholic versions; Islamic; and secular values embedded in the curriculum of differently sponsored schools. It was perhaps for this reason that the Australian government sponsored a national values education program in an attempt to develop common Australian values for all schools.

Content and values, representing the core of any curriculum, differ across nation-states and reflect a great diversity, depending on the economic, social, and political needs of individual countries. The school curriculum becomes an important mirror that reflects what is seen to be important by individual countries, and differences between countries can be judged by the images reflected in such a mirror. An important question that remains to be addressed is what these differences mean and in particular what they can mean for individual students who experience them on a day-to-day basis.

### Equity Issues

Deciding who has access to which knowledge often leads to consideration of equity. Thus, providing students with access to technical knowledge and skills that can help them participate in the knowledge economy provides an advantage for both individuals and their respective societies.

Such an outcome does not exhaust the limits of the curriculum, but it is an important contribution to both personal and social well-being. In other contexts, such as agricultural and subsistence economies, the kind of curriculum that is provided will serve local needs and be praised for its relevance, but it will rarely take students beyond the local. In both cases, the curriculum serves an important social function, but with different outcomes for students. This is not so much the fault of the curriculum but it is a reflection of the social and economic contexts that construct the curriculum in different locations. Many curriculum theorists argue that an important task of the curriculum is to try to break this reproductive function that rarely leads to change in the economic and social circumstances of individuals. When viewed internationally it is possible to appreciate the pervasiveness of this reproductive function and the different forms it takes. It is clear that just such a link creates gross inequity in the international distribution of resources when the curriculum of some schools links students to the benefits of a knowledge economy while other students are linked to the ongoing demands of a subsistence economy.

Within societies, the school curriculum might be adjusted and fine-tuned to try to ensure more equal outcomes for all students, but this is almost impossible to achieve across countries. Global interconnectedness might be seen as one way to ameliorate unequal outcomes but the benefits of processes such as globalization are also unequally distributed across countries. This highlights the point that curriculum priorities are more likely to be concerned with local priorities than global priorities—there is little evidence across countries that globalization leads to uniformity or standardization of the school curriculum. Indeed the opposite is the case—globalization is more likely to exacerbate curriculum diversity so that as post-industrial countries develop more in that direction so too will their curriculum become differentiated from that of countries not moving in that direction. Curriculum differentiation and diversity are likely to remain the key trends for the school curriculum when viewed from an international perspective and this will continue to produce unequal educational outcomes across the globe.

The school curriculum has achieved important results for many students across different countries.

Programs of study, different as they are in different national and cultural contexts, serve the purpose of opening up new worlds of learning and understanding for many young people. Yet the curriculum is not divorced from the social, political and economic contexts that construct it. This means local priorities will always be dominant, outcomes will differ across national boundaries, and some students will be more advantaged than others. There are many continuing attempts both nationally and internationally to try to ameliorate these conditions by making the curriculum more responsive to achieving equity and social goals (e.g., through international agencies such as UNESCO and reform-minded national governments). Yet the school curriculum does not create these conditions and is always a response to them: It does not act independently. There is little doubt that across countries the school curriculum can be a force for good and social progress. Yet its relation to local priorities, its concern with relevance, its need to service social purposes, and the extent to which it is embedded in political and economic processes ensures that aspirations for the curriculum will always be bounded by these realities. Curriculum reform is often a signal from policy makers that these boundaries can be broken. Reform affirms the faith that policy makers, practitioners, and theorists have in the efficacy of the school curriculum. In this sense the school curriculum from an international perspective remains a significant option to achieve change. The capacity of the school curriculum cannot be underestimated, just as the realities that constrain it cannot be ignored. This is the real tension that is sparked by the school curriculum and one that will continue to be challenged in order to achieve better outcomes for all students irrespective of the countries in which they happen to reside.

## INTERNATIONAL RESEARCH

---

In conventional curriculum inquiry, there has been a tendency to study curriculum as locally and nationally distinctive. Nonetheless, international research in curriculum studies has often been pursued using comparative and historical approaches, transcending national boundaries. The focus in this entry is on the basic approaches to and issues highlighted in international comparative curriculum research, including international curriculum discourses, internationalization of curriculum studies, and transnational curriculum inquiry.

### Basic Approaches and Issues

One of the basic issues in international comparative curriculum research is the extent to which one nation's curriculum and its curriculum-making processes can be explained by a common international or global context and to what extent the particular sociocultural contexts of single national systems should be taken into account. Moritz Rosenmund, for example, has analyzed different levels of and approaches to curriculum research with regard to structures and procedures of institutional regulation in curriculum and curriculum-making processes. He suggested that the curriculum process in a particular society is subject to the interplay between the continuum of two forces suggested by Talcott Parsons: context-specific particularism and culture-free pluralism. These could be explained further from various perspectives ranging from a social cohesion perspective (based on theory of societal system), a sociostructural perspective (based on class and status theories), a

world system perspective (based on world-system theory), and administrative rationality (based on organization theory).

### Social Cohesion Perspective

The social cohesion perspective highlights the curriculum process being embedded in the specificity of institutional arrangements, structural relationships, and symbolic representations forming a totality in individual societies. A review by Stephen Heyneman and Sania Todoric-Bebic revealed that different regions, however, may have various issues related to structural approaches to social cohesion. In Sub-Saharan Africa, the structural approaches to social cohesion highlight equality of opportunity, universal primary education as well as administration, organization, and school governance toward the goal of democracy, and teachers' role in political socialization. In Asia, there are variations in such approaches: Malaysia has adopted schooling for national identity; India, Indonesia, and Malaysia have highlighted the role of moral education in enhancing social cohesion. Textbooks and examinations are used as vehicles for social cohesion in China and for the promotion of homogeneity in Japan.

### Sociostructural Perspective

For the sociostructural perspective, the reproduction of social inequality and cultural capital through school education and its curricula has been discussed by a number of scholars, including Basil Bernstein, Michael Apple, Pierre Bourdieu, and Michael Young. Bernstein, in the 1970s, introduced the concepts of strong and weak classification and framing of curricula. Classification relates to the construction and maintenance of boundaries and the hierarchy of curriculum or subject content while framing refers to the relative extent of control by the teacher and pupils over the selection and transmission of knowledge. Bernstein proposed the collection code curriculum (strong classification and strong framing) and the integrated code curriculum (weak classification and weak framing). For the collection code curriculum, he quoted the English upper secondary and Advanced level (post-16) courses that tended to be specialized, concentrated on a small number of related subjects

while the U.S. counterpart tended to be less specialized and structured by courses defined as knowledge units, and continental European curricula structured by subjects. He noted that there was a trend in many countries to move toward an integrated code curriculum, characterized by an enquiry-based approach to topics and themes, multiple modes of assessment, and a wide choice of subjects and courses for pupils and teachers working in interdependent teams. In addition, counteracting the possible deterministic and hegemonic nature of cultural reproduction theories, Bernstein, in *The Structuring of Pedagogic Discourse* (1990), argued that there could be two recontextualizing fields: the official recontextualizing field focusing on the what of pedagogic discourse and the pedagogic recontextualizing field highlighting the how of pedagogic discourse. These two fields could provide the potentials for various stakeholders such as government officials, consultants, school practitioners, publishers, and university experts to change and negotiate the discourses for curriculum planning, curriculum change, and knowledge transmission.

### *World System Perspective*

From the world system perspective, Robert Fiala and Gordon Lanford's examination of formally stated aims of education between 1950 and 1970 in various countries revealed a world level ideology of education, which focused on the development of the individual, the economy and the nation. Fiala has analyzed the educational aims for countries worldwide between 1955 and 2000, showing that the development of the individual (especially his or her personal and emotional development) tended to be more prominent among educational aims followed by more emphases on national development (aims related to citizenship and national identity) and economic development (but not on sustainable development) as well as normative aims of equality, democracy, and education as a human right and employability as an aim of education.

In addition to educational aims, curriculum structure, standards, and subject offerings have been subjects for analysis. John Meyer and his colleagues' research in the 1990s and recent work of Aaron Benavot, for example, illustrate a trend toward broad similarities in the structure of primary school curricula across nations and over

decades. Such a world curriculum generally consisted of one or more national languages, mathematics, science, some form of social science (e.g., social studies, history, geography, civics), and some form of aesthetic education (in arts and music), and physical education. It is likely that such a trend toward standardization is driven by the networking of international organizations and associations and the promotion by individual countries of universal values such as human or civic rights, socioeconomic development, or education.

### *Administrative Rationality*

For administrative rationality, Henning Haft and Stefan Hopmann used the case of Prussia to illustrate the mechanics of curriculum administration as symbolic actions, which included compartmentalization, licensing, and segmentation for providing legitimation and differentiation of the social distribution of knowledge. Compartmentalization in its current forms entails, for example, a separation among subject syllabus, curriculum timetables, and examination regulations by differentiated agencies. Licensing refers to separation of executive responsibilities such as instructional planning and teaching at school or classroom level from the planning authority of state-run curriculum development. Finally, segmentation of the levels of discourse relates to the division of ways and means in communications between curriculum construction by government officials and experts and curriculum debate by the public.

Although the social cohesion and sociostructural perspectives shed light on the importance of societal systems and social structures in shaping curriculum policies and changes, Ivor Goodson has pointed out that many Western writers on educational and social changes have ignored personal missions and biographical trajectories of key personnel. These create unexpected effects of symbolic actions in curriculum decision making and policy implementation under the administrative rationality perspective. A recent good example is found in Craig Kridel and Robert V. Bullough's recent work on stories of the Eight Year Study in the United States. These provided enlightening biographical narratives of nine educators who contributed to educational reform through experiment, exploration and discovery. In addition to

personal influences, Goodson highlights curriculum change that involves the interactions between domination and structure as well as between mechanism and mediation, all being located within historical periods. Nonetheless, many studies of curriculum and schooling tended to be conducted within snapshots of time and context. He examines how and why, from sociopolitical and social constructionist perspectives, some school subjects historically evolve and maintain their traditions in the grammar of schooling.

Some scholars, on the other hand, have addressed the profound influences of culture and ideologies on curriculum. In the context of England, Dennis Lawton refers to the interplay of three basic educational ideologies: classical humanism, progressivism, and reconstructionism. He refers to the use of cultural variants or cultural subsystems (sociopolitical system, economic system, communication system, rationality system, technology system, morality system, belief system, aesthetic system, and maturation system) in analyzing school curricula. In a similar vein, Alistair Ross examines the interplay of three curriculum traditions, namely, the academic, the utilitarian and the progressive, in English curriculum development and history. Robin Alexander, on the other hand, conducted international comparisons of primary education in France, Russia, India, the United States, and England. When comparing teaching in these five cultures, central European, Anglo-American, and Indian traditions could be identified. Differences could also be discerned with regard to: the openness of the lesson timeframes; handling and focus of lesson beginnings and closures; and unitary or episodic character of the body of the lesson. Moreover, the highest levels of distraction occurred in American and Indian classrooms. Although American students misbehaved or took part in some conversations during the lesson, Indian students stopped working, sat passively holding their pens, and watched the blackboard if they did not follow the lesson.

### *Additional Approaches*

As regards methodological issues related to context-specific particularism and culture-free pluralism, Rosenmund proposed two approaches for international comparative curriculum research. First there was the comparison and contrast

method based on Max Weber's ideal types concept. Second, there was the discourses method based on W. H. Schmidt and his colleagues' work on mathematics and science teaching in several countries. For the comparison and contrast method, the steps were the reconstruction of curricular processes in different countries as distinct forms of national curricular processes interacting with particular contexts; inference of types of regulation and patterns of relevant contextual conditions; exploration of particular historical and institutional factors shaping the variation of types and patterns of contextual conditions shaping curriculum processes; and using ideal types for comparing and contrasting societal conditions. An interesting example of this procedure can be found in a historical symposium in 1988 on a cross-cultural comparison of the Eight Year Study in the United States and the Humanities Curriculum Project in the United Kingdom. Some hypotheses were formulated based on similarities in notions of success and failure, manifestations of progressive education, emergence from climates of unease on the one hand and differences in strategies for coping with the unease, promoting curriculum change, and designing specific forms of curriculum evaluation.

### **International Curriculum Discourses**

The discourses method involves researchers from different countries offering interpretations of specific curriculum and teaching concepts from their own culture-specific perspectives, which, after rounds of negotiation and discussion, arrive at a common or consensual understanding of concepts with defined operational definitions. This approach is exemplified by international survey and observation studies such as the Trends in International Mathematics and Science Study (TIMSS) and the International System for Teacher Observation and Feedback (ISTOF) led by Charles Teddlie, Bert Creemers, Leonidas Kyriakides, Daniel Mujis, and Fen Yu.

Curriculum change and implementation take place at various levels ranging from the government, region or province, district, school, and teacher levels even within a single national system. Although there may be gaps and discrepancies between levels, schooling—its subjects, teaching and learning, schools, probably with exception of

programs of study—may be broadly more similar than different across societies. And the broad similarities of schooling in different societies mirror the linkage between the local implementation and universal discourses and issues that emerged. The ultimate questions are as follows: Who has the power at which level to decide upon the curriculum aims, contents, and modes of delivery for whom and how? Is it necessary to have equivalent curriculum concepts and indicators within and across various stakeholder groups among different countries for making international comparisons? As regards the unit for comparison, while national education systems and school systems remain important in future curriculum studies, Andy Green pointed out that diasporic language groups, distributed teacher and student communities, and virtual communities could be subjects for future comparative educational studies.

### Internationalization of Curriculum Studies

William Pinar reviewed the field of curriculum studies since 1950. He suggested that U.S. curriculum theory was structured on three historical moments: the crisis of curriculum development (1918–1969); reconceptualization from curriculum development to understanding curriculum (1980 to the present), and internationalization (2000 to the present). In addition to comparative curriculum research, international curriculum inquiry could be facilitated through enriching curriculum discourses through different cultural or cross-cultural perspectives. As early as 1999, the *Journal of Curriculum Theorizing* had published the section “International Curriculum Discourses.” The issues of identity for teachers working in a global context were explored from the perspectives of Christianity, Foucauldian theory, Confucianism, the Trickster tradition, and Buddhism. David Gregory Smith asserted that internationalization of curriculum work could not be achieved simply by celebrating differences; a collective global identity could be constructed by different peoples of the world genuinely sharing and debating their wisdom on how to live in a better, future, and shared world. Pinar has suggested that internationalization of curriculum studies needed to address both the horizontality and verticality of the field: the former ranging from the global to the local and the latter embracing historical and

future-oriented studies across national, regional, and global levels. He also remarked that in terms of themes of inquiry, the field of curriculum studies tended to highlight school improvement, and more emphasis could be put on understanding curriculum theory and history, including curriculum development and evaluation.

### Transnational Curriculum Inquiry

*The Journal of Curriculum Studies* published articles mainly from the English-speaking world in the 1970s, but gradually spread to continental Europe and beyond in the 1980s and the 1990s. Against the backdrop of globalization, some curriculum scholars such as Noel Gough assert that globalization is a transnational imaginary in which national spaces and identities as well as economic boundaries are undone and become homogenized. He argues that internationalization of curriculum inquiry should facilitate the performance of local knowledge traditions and ways of knowing in curriculum inquiry rather than emphasizing the translation of local representations of curriculum inquiry into universalized discourses and practices. This is to some extent actualized by the publication of a new journal, *Transnational Curriculum Inquiry*, in which articles from non-Western sources such as China, Japan, and Portugal have been published with peer comments. In addition, John Meyer has encouraged us to give more attention to some ignored themes in curriculum discourses including nationalism, religion, national ontology (particular properties of national spaces), social structure (e.g., tracking of students and curriculum differentiation) as well as concrete and local knowledge.

## INTERTEXTUALITY

---

The term *intertextuality* was introduced by Julia Kristeva to mean that any given text does not stand independent of other texts, events, or objects, but interacts with those to produce a mosaic of ideas. Kristeva was working off of Mikhail Bakhtin's notion of dialogism, which explains the primacy of context over text, the hybrid nature of language, and the relation among utterances. Both Bakhtin and Kristeva suggest a three-part nature of textual dialogue: The act of interpretation involves not just author and addressee, but a third entity as well, a super-addressee. The superaddressee term expands earlier theories of textuality such as formalism by problematizing the concept of the closed text since

a wide variety of influences is always streaming in from outside social discourses.

The significance of this move away from fixed dialogue to open discourse is central to the field of curriculum studies, which William Pinar describes as a complicated conversation. No longer can we read a text or view a film without becoming aware of embedded meanings, sometimes heard only as undertones. If, as Louis Althusser observed, we are always already positioned by semiotic systems, then it becomes the task of the curriculum theorist to lay bare the prepositions. The province of the curriculum theorist interrupts assumptions about uncomplicated interpretations. Meaning making as an act of interruption can therefore be subversive or it can be illuminating and playful. In a culture of mass consumerism with access to the World Wide Web, it is essential to be able to read texts in all their various forms so as to see (and hear) how these shape agendas.

Here is where the work of curriculum studies becomes necessary, even unique, among disciplines. Pinar and Madeleine Grumet have argued that curriculum is a moving form, based on the root meaning of *currere*; its focus is on that which flows within subjects. How can curricular theorists ignite sparks in their students and from their publications so as to explore how subjectivities have been positioned? Such a project is both reflective and active, critically engaging outside social forces in complicated conversation.

Intertextuality can be seen as a verbal or gerundive enterprise that contextualizes any text (including the self) by blurring, parodying, layering, remaking, and so on. Intertextuality is a living pedagogy, the very nature of curriculum studies, which turns to such studies as women and gender, psychoanalysis, place, spirituality, post-colonialism, history, auto- or biography, institutionality, and aesthetics in order to examine the plurality of forces that come in to play on subjects and within texts. Of these studies, cultural studies is perhaps the latest and most explosive of areas; unusual, taken-for-granted, seemingly innocuous objects are meaning shapers. Consider Barbie for understanding gender training, gaming for understanding teen violence, and tattooing for understanding body art: These can be seen as a horizon against which curriculum studies critiques the social milieu.

Literature may be one of the oldest forms of intertextuality, as old as the Bible itself with its cross referencing between Hebrew and Christian scriptures. Two examples of postmodern literature illustrate. The British playwright Tom Stoppard is wickedly intertextual, deliberately pilfering characters from, most notably, Shakespeare, who himself pilfered plots from earlier tales. *Rosencrantz and Guildenstern Are Dead* is a direct reference to two minor characters from Shakespeare's *Hamlet* who take center stage in Stoppard's farcical rewrite. Stoppard's theme—what we witness is unrelated to truth—always challenges the respect with which we view sacred cows. In Toni Morrison's *The Bluest Eye*, the Dick and Jane readers of 1940s middle-class, White, heterosexual America are juxtaposed against the main storyline of an ugly, poor, Black child who only wants to be blond, blue-eyed, and White like the iconic Shirley Temple. Morrison disrupts accepted coded notions of beauty, class,

identity, and race through her skillful weaving of intertextual references.

## JACKSON, PHILIP W.

---

Philip W. Jackson achieved prominence first as an educational psychologist, then as an observer of classroom life, and later as a philosopher of education. Throughout his career, he contributed seminal work to the field of curriculum studies. In deceptively simple prose, he has argued that the unintentional curriculum is as worthy of study as is the official curriculum; that the study of curriculum is healthiest when it draws on many perspectives, including its own history; that efforts to define curriculum prescriptively have been more provocative than instructive; and that the moral nature of teaching is a necessary starting point for curriculum studies.

After receiving his PhD from Teachers College, Columbia University, in 1955, Jackson joined the faculty of the University of Chicago (where he remained until his retirement in 1998). Initially known for his work (with Jacob Getzels) on giftedness and intelligence, Jackson began to look for ways to get closer to the phenomena of schooling than he could get through the examination of data sets generated by student responses and performances. He spent months as an observer in classrooms, and his reflections on these observations appeared in *Life in Classrooms*, a book that inspired generations of curriculum scholars to pay more thoughtful attention to the complexities and uncertainties of classroom life. Jackson showed that the hidden curriculum was a powerful shaper of student experience and that much of the most

significant and most lasting student learning was being missed by the ordinary methods of educational research.

In “Curriculum and Its Discontents,” a paper first delivered in 1979 to Division B of the American Educational Research Association, Jackson addressed the recurring criticism (launched by Decker Walker and Joseph Schwab in the 1960s) that the field of curriculum was moribund (or already dead). Jackson questioned both the value of the metaphor of the dying field and the helpfulness of the responses to the supposed crisis. Acknowledging the freshness brought to curriculum study by existential, phenomenological, Marxist, psychoanalytical, literary, and philosophical thought (some of which had been inspired by *Life in Classrooms*), Jackson nevertheless critiqued the tendencies of the new perspectives to become bogged down in jargon and to be dismissive of earlier traditions and methodologies of curriculum studies. These concerns with making the products of curriculum study readable and with reconciling opposing views of curriculum and curriculum study recur throughout Jackson’s work.

In “The Mimetic and the Transformative” (the concluding essay from *The Practice of Teaching*), Jackson sketched two competing traditions of teaching that are based on two contradictory conceptions of knowledge. In the mimetic tradition, knowledge is information and skills that are transmissible, testable, and forgettable; they are moved from teacher to student through a sequence of routine steps—test, present, perform, assess, remediate (if necessary), and move on. In the transformative

tradition, knowing cannot be separated from living; to learn is to be fundamentally and pervasively changed, and there are no routine steps to guide the teacher. These two conceptions of knowledge imply two starkly different definitions of curriculum, perspectives on the nature of curriculum study, and roles for curriculum specialists. But, in keeping with his habit of reconciling opposing points of view, Jackson argues that the two traditions can be mutually supportive, suggesting that curriculum studies also need to be guided by both traditions.

In 1992, in *The Handbook of Research on Curriculum: A Project of the American Educational Research Association*, Jackson made two contributions that have helped to shape the study of curriculum. The first is the book itself—the range and quality of the contributions edited by Jackson. The handbook immediately became the standard in the field and has been used as a reference point for more recent curriculum handbooks.

The second contribution Jackson made in the handbook was his essay, “Conceptions of Curriculum and Curriculum Specialists,” an overview of curriculum studies in the 20th century. The essay examines debates over definitions of curriculum, contending perspectives on the nature of curriculum studies, and the evolving roles of the curriculum specialist. Acknowledging the confusion surrounding the study of curriculum, Jackson argues that a primary reason for the confusion can be traced to the assumption that one definition, one perspective, or one role must be seen as superior to other competing definitions, perspectives, and roles. This assumption, says Jackson, is unnecessary and serves only to exacerbate divisions among curriculum specialists and to add to the sense of confusion about the nature and purpose of curriculum studies.

In 1993, in *The Moral Life of Schools*, Jackson returned (together with David Hansen and Robert Boostrom) to themes he had first explored in *Life in Classrooms*, including unintentional learning and the lasting significance of everyday events. But *The Moral Life of Schools* also manifests the transformation of Jackson’s scholarly perspective from quantitatively minded educational psychology to philosophy of education. The tables and statistics that carry much of the argument in *Life in Classrooms* are absent from *The Moral*

*Life of Schools*, replaced by extended passages of observation and reflection. Examining teachers with painstaking care, Jackson reveals both his sympathy for their work and his unwillingness to allow even a minute aspect of it to escape thoughtful attention. The result of the analysis is a conviction that the moral world created by the teacher is the most important curriculum element in any classroom, for it is both a lesson itself and a matrix from which all other lessons are formed.

During his long career of teaching and writing, Jackson more and more has drawn on literary and philosophical sources outside those traditionally used by curriculum scholars, demonstrating in his work an expansive view of curriculum studies that has come to characterize the field.

## JOURNAL OF CRITICAL INQUIRY INTO CURRICULUM AND INSTRUCTION

---

Founded in 1997, the *Journal of Critical Inquiry Into Curriculum and Instruction*, a refereed journal, was committed to publishing educational scholarship and research of professionals in graduate study. The journal was distinguished by its requirement that the scholarship be the result of the first author’s graduate research—according to

*Cabell's Directory*, the first journal to do so. In addition, the third issue of each volume targeted wide representation of cultures and world regions, often including text in the author's first or national language (e.g., vol. 1). The journal published three issues per volume, a total of 15 issues between 1998 and 2004, when funding, international distribution, and relocation of the editor dictated discontinuation.

Initially sponsored and published by the Wichita State University, Kansas, by volume 2, Caddo Gap Press, San Francisco, published the journal. Later, Georgia Southern University also sponsored the journal.

Features of the publication included a conceptual frame "From the Desk of the Editor" introducing the focus of the journal, "Foreword" introducing the focus of the issue, and "Afterthought" making interpretations and suggesting implications of the content taken as a whole. The latter two were written by members of the editorial advisory board. "Current thinking on . . ."—also written by members of the board—highlighted state-of-the-art topics related to the issue's themes. Other aspects of the journal included the following:

- illustrations, photography, collage, student-generated art or artifacts, full-color art;
- cutting-edge methodologies extending educational research through aboriginal and native oral traditions (e.g., autobiographical work in vol. 2, issue 2 by Kuloin), arts-based analysis, found poetry (e.g., Cherice Montgomery's critical review in vol. 4, issue 2, of Barone's *Touching Eternity*); and
- foci on liberatory pedagogy and social justice action research.

The journal was also the first publication to feature G. Pritchey Smith's expanded knowledge bases for diversity in teacher education in volume 2, issue 3.

The synergy arrow on the cover of the journal translated into the journal's acronym, *JCI*~>*CI*, representing the belief of those working on the journal that their combined efforts with those of scholars in the field would far exceed the sum of individual efforts. The concept also appeared in the regular feature "On the Shoulders of Giants"—Bernard of Chartres' metaphor of dwarfs on the

shoulders of giants, seeing more because of being lifted high.

## JOURNAL OF CURRICULUM AND PEDAGOGY

---

The *Journal of Curriculum and Pedagogy* is a biannual publication sponsored by the Curriculum and Pedagogy Conference. Patrick Slattery and James G. Henderson developed the idea and with the financial support of Texas A&M and Kent State University, started the journal in 2004. The journal honors the interdependence of varied perspectives, research, scholarship, and forms of representation in order to achieve richer and more complex opportunities for curriculum workers to explore the relevance and significance of their efforts.

The journal offers two unique elements when compared to other curriculum journals. First, it provides spaces for arts-based researchers to share their work both within the journal and on its cover. Each issue of the journal includes an arts-based work, and the cover of the journal for each issue includes a photograph or work of art that coincides with an arts-based article. This element of the journal represents a vital partnership that began between the Curriculum and Pedagogy Conference and the Arts-Based Educational Research Special Interest Group of the American Educational Research Association (ABER SIG) in

2000 during the conference's first annual meeting. At the time, ABER met jointly with Curriculum and Pedagogy, and since that time the conference has maintained an arts-based strand at each annual conference.

Second, the journal maintains a "Perspectives" section in each issue. In this section, the editors identify a key question or issue in the field and seek a variety of very diverse leaders in the field who provide responses. 'Perspectives' sections have included such issues as how spiritual, moral, and theological discourses influence curriculum and pedagogy; how curriculum workers can claim a progressive curriculum and pedagogy in a politically conservative climate; how the arts inspire curriculum and pedagogy; and how curriculum scholars can become public intellectuals. The editors who plan and develop each "Perspectives" section actively seek diverse perspectives in order to provide engaging and complex conversations about the questions and issues.

The mission of the journal focuses on intersections between curriculum theory, the study of teaching practice, and the professional artistry that emerges within those intersections. The journal considers these intersections democratic spaces based upon the core ideals of John Dewey and his notions of experience, community, and creative expression. Therefore, the journal's editors strive to move away from simple solutions by encouraging conversations between scholars and practitioners who use varied forms of inquiry: historical, theoretical, theological, and philosophical analysis; arts-based research; linguistics; autobiography; and scholarship addressing issues of gender, sexuality, race, and ethnicity.

The journal attempts to bring honest challenges to the field so its readers can critically explore problems and possibilities within K–12 classrooms, within teacher education programs, and within the larger society. To this end, the journal recognizes the need to honor diverse perspectives, multiple forms of inquiry, and both interdisciplinary and transdisciplinary boundaries within its pages. However, the journal does not merely provide parallel spaces for these diverse views and varied forms of inquiry. It also seeks tensions and intersections between and among them.

## *JOURNAL OF CURRICULUM AND SUPERVISION*

---

The *Journal of Curriculum and Supervision* (1985–2005) was a quarterly journal of theory, inquiry, and analysis in the scholarship and practice of the fields of curriculum and supervision. Published by the ASCD (Association for Supervision and Curriculum Development), the journal began with the fall 1985 issue. ASCD Executive Editor Ron Brandt stated in introducing the journal that ASCD was creating the most widely circulated English-language scholarly publication on curriculum and supervision in the world. Brandt attributed the journal to a history of recommendations begun in the late 1950s and culminating with a plan for increased attention to research and theory. The journal began publication with Edmund Short and Robert F. Nicely Jr. as editors and O. L. Davis Jr. (Davis also was editor of the journal from 1995–2005), Maxine Greene, Thomas Sergiovanni, Arthur Steller, Decker Walker, and Benjamin Williams as editorial board members. The editorial board chose the name of the journal and specified that it would be a refereed scholarly journal that examined curriculum and supervision practices and related policy issues. The journal invited articles from a wide variety of appropriate research methods, including interpretive, empirical, historical, critical, and analytical.

The journal continued its 20-year history with largely the same publication intent. Its masthead statement in the final year of publication, 2005, stated that the journal was a refereed scholarly journal that reflectively examined curriculum and supervision policies and related issues as they pertained to teaching, learning, and leadership. Studies using a variety of appropriate research and inquiry methods were accepted for publication.

During its publication life, the journal reported, served as forum for, and felt the impact of changing paradigms in curriculum and supervision. In 1985, supervision was an expected and respected role and professional practice, and clinical supervision was

the model paradigm. The purpose of supervision was to ensure reasonable practice-based compliance and fidelity to curriculum and instructional initiatives within schools and districts. During the two decades of the journal's publication, competing paradigms first moved supervision from expert-based clinical supervision to more collegial developmental models, then to more democratized and peer-based coaching and learning community models. The conceptual shift led to identity issues within the field and scholarship of supervision. This intellectual and practical shift in the field was catalogued by Short as part of a report on the journal's first 10 years. He reported that 31 of 80 articles on supervision had been on either conceptual or philosophical issues in supervision. In a similar manner, the publication years of the journal witnessed the continued movement of the curriculum field from emphases on curriculum practice and curriculum development to curriculum studies and the influence of critical theory in the field. Short's review indicated that 20 articles published on curriculum—by far the largest proportion—in the journal were theoretical or philosophical.

There also were different views of the journal's role. ASCD Executive Gordon Cawelti saw the journal as a potential outlet for definitive and practice-changing research studies that could be promoted as policy and practice contributions by the parent organization. This view was consistent with ASCD's move toward increased lobbying and development as a major education publishing house. Contributors and other members of the higher education community, however, viewed the journal as an outlet for the broad array of topics and inquiry modes listed on the masthead guidelines. ASCD's decision to suspend publication after the 2005 volume year was attributed to diminished circulation (revenue) that no longer justified publication expenses.

## JOURNAL OF CURRICULUM STUDIES

---

The *Journal of Curriculum Studies* (*JCS*) is an international, peer-reviewed journal with editorial offices in the United Kingdom, Canada, the United States, and Australia. *JCS* focuses on promoting a global examination of curriculum issues and an interdisciplinary understanding of curriculum practice that emphasizes a cross-cultural dialogue. It maintains an interdisciplinary approach to curriculum studies by featuring articles that focus on the intersections of theory, research, and practice.

The journal was established in November 1968, and the founding editor was P. H. Taylor from the School of Education at the University of Birmingham, in Edgbaston, United Kingdom. Its first issue included pieces by Lawrence Stenhouse and John Goodlad. *JCS* widened its scope by calling for papers that deal with the history of the field, teacher education, and the planning, policy making, and evaluating of curriculum. The journal features reports on the status of curriculum from various parts of the world, op-ed pieces, speculations, and book and essay reviews. *JCS* also collected articles into themed issues on topics such as ways of seeing, knowing, and teaching; written curriculum guides; and changes in curriculum. *JCS* is published six times a year.

In 2007, Ian Westbury and Geoffrey Milburn published an edited collection of seminal *JCS* articles written in the past 25 years, including William A. Reid's "Strange Curricula: Origins and Development of the Institutional Categories of Schooling," David Hamilton's "Adam Smith and the Moral Economy of the Classroom System," Agneta Linne's "The Lesson as a Pedagogic Text: A Case Study of Lesson Designs," Max Van Manen's "Reflectivity and the Pedagogical Moment: The Practical-Ethical Nature of Pedagogical Thinking and Acting," Wolfgang Klafki's "Didaktik Analysis as the Core of the Preparation of Instruction," J. T. Dillon's "Effect of Questions in Education and Other Enterprises," Jeremy N. Price and Deborah Loewenberg Ball's "There's Always Another Agenda': Marshalling Resources for Mathematics Reform," James P. Spillane, Richard Halverson, and John B. Diamond's "Towards a Theory of Leadership Practice: A Distributed Perspective," Joan Solomon's

“Meta-Scientific Criticisms, Curriculum Innovation, and the Propagation of Scientific Culture,” John Elliott’s “A Curriculum for the Study of Human Affairs: The Contribution of Lawrence Stenhouse,” James Andrew Laspina’s “Designing Diversity: Globalization, Textbooks, and the Story of Nations,” Brent Davis and Dennis J. Sumara’s “Curriculum Forms: On the Assumed Shapes of Knowing and Knowledge,” and Shirley Brice Heath and Milbrey Wallin McLaughlin’s “Learning for Anything Everyday.”

## JOURNAL OF CURRICULUM THEORIZING

---

The *Journal of Curriculum Theorizing* (*JCT*) has served as the major publication for reconceptualist curriculum theorists since its inception in the late 1970s. Initially, the journal served as a vehicle for publishing particularly noteworthy papers presented at the curriculum theory conference that in 1983 became known as the Bergamo Conference. Interspersed with the conference papers during the first few years of the journal were original manuscripts by some of the leading figures in reconceptualist curriculum theory such as William Pinar, Paul Klohr, James Macdonald, and Ted Aoki as well as the generation of curriculum theorists, such as Janet Miller and Madeline Grumet, who had been mentored or influenced by these scholars as they completed their doctoral studies in the 1970s and early 1980s. The first issues of *JCT* might be considered primitive, aesthetically and technically, by today’s standards, but the journal carved out an important theoretical niche and filled a void that had been left by more established curriculum journals such as *Curriculum Inquiry* and *Educational Leadership*.

The *JCT* has always viewed itself as a voice for curriculum theorists who were exploring new and uncharted territory in the field. The journal generally eschewed traditional forms of inquiry and research and allowed its authors to be both experimental and intellectually curious. Manuscripts drew largely from philosophical, historical, sociological, theological, and psychoanalytic paradigms and when a research design was used, it was qualitative. Although these modes of inquiry are commonplace today, in the late 1970s and 1980s they were far from the norm and were only occasionally evident in the traditional, mainstream educational journals of the time. But that was the primary mission of the journal: to make the strange familiar and the familiar strange.

By the late 1980s and 1990s, *JCT* began to utilize more aesthetically oriented formats on both the cover pages and in the articles. Original drawings, artwork, photographs, and other types of illustrations appeared. The journal began to divide articles by sections such as “Literary Anthropologies,” “Curriculum Forms,” “Hermeneutic Portraits,” and “Cultural Product Reviews,” in addition to the usual four or five articles. This division allowed writers and readers the opportunity to explore alternative approaches to curriculum theorizing while providing a place for new theoretical perspectives to emerge.

This organizational structure has continued through the 1990s and into the current format, although new section titles have evolved including “Biblio-Reverence,” “Childhood and Cultural Studies,” “International Curriculum Discourses,” “Literacies,” “[Popular] Cultural Matters,” “Reading Between the Lines: Perspectives on Contemporary Cultural Texts,” “Reconceptual Inquiries in Practice and Politics,” “Post-Structural Lines of Flight,” “Studies in Philosophy, Ethics and Education,” and “Feature Articles.” The most recent section titles suggest that the journal is organic, vibrant, and constantly changing to reflect changes in the field and more avant-garde directions.

Although the subscriptions for *JCT* have been primarily from university libraries and attendees of the Bergamo Conference, the readership has remained steady over the past 30 years despite the emergence of new journals focusing on curriculum studies, international curriculum perspectives, and

curriculum and pedagogy. The *JCT* has established and maintained a strong niche in the field of curriculum theory and has provided a voice for several generations of curriculum theorists.

## JOURNAL OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF CURRICULUM STUDIES

---

The *Journal of the American Association for the Advancement of Curriculum Studies* began its online publication of articles and research essays on subjects important to the intellectual advancement of U.S. curriculum studies in 2005. Edited by Alan Block of the University of Wisconsin-Stout, it serves as the main voice of its parent association, which aims to advance the field of curriculum studies in two ways: in terms of maintaining and promoting the importance of a formal curriculum studies field and in terms of placing curriculum studies in an international frame of reference.

Because curriculum studies as a subfield of educational studies emerged historically within the larger discipline of education and now permeates multiple disciplines, articles and essays published by the journal pay careful attention to cultural issues and methodological concerns in order to understand curriculum as many kinds of texts including, but significantly extending beyond, curriculum as administrative text. The importance of this conceptualization of advancement extends to institutional issues at the tertiary level; this includes, for example, the consideration of the politics of placement, of where, when, and how

curriculum studies exists as an independent arena of research and teaching, as well as an organizing concept within or across departments. At the same time, the American Association for the Advancement of Curriculum Studies has an interesting perspective on the internationalization of the field of curriculum studies as one of a number of regional and national affiliates of the International Association for the Advancement of Curriculum Studies. Thus, articles and essays examine how the field of curriculum studies exists and operates in particular locales, analyze curriculum histories in cross-national perspective, or investigate the relationships among curriculum formation, epistemology, ontology, governance, and state formation in international perspectives. The journal also routinely publishes the text of the invited presidential address—a keynote presentation invited by the current association president—from its annual conference.

The unique character of the journal arises in its preference for research essays constituted by close readings of published texts in curriculum studies. These research essays not only critique, but also contextualize new scholarship in the history and present circumstances of the field, institutionalizing complicated conversation between past and present as well as between U.S. curriculum studies and the work in other locations. With the book(s) and article(s) or essay(s) situated at the illusory center, the *Journal of the American Association for the Advancement of Curriculum Studies'* research essays explore not only ideas in these texts, but also their relations to culture, society, and the historical moment.

## JOURNAL OF WORLD COUNCIL FOR CURRICULUM AND INSTRUCTION

---

The *Journal of the World Council for Curriculum and Instruction* (WCCI) has played a major role in accomplishing the transnational organization's goal of networking with educators worldwide. In 1982, WCCI started serious planning to make the journal a reality. After several years of discussion and planning, the journal was born. In 1986, Virginia (Jean) Floresca-Cawagas was invited to become the first editor. She accepted and served from 1987 to 1990. In addition, Tony Hepworth served as the first associate editor. The first WCCI journal issue was published in June 1987 under the title of *WCCI Forum*. The journal was originally intended as a two-issue per year publication, but funding and distribution to the large international body of members would continue to plague the publication. In addition, editors faced the challenge of the WCCI mandate to balance scholarship and equitable representation of authors by world region.

In 1991, a new editorial staff was formed. Henry Evans and Helene Sherman served as editors. Marcia Lipson and Nondita Mason served as the associate editors. They published one issue, *WCCI Forum*, volume 5, numbers 1 and 2, in 1991, with Mason and Sherman as editors. Then the journal was relatively inactive from 1992 to 1998.

In 1998, the WCCI executive board invited Floresca-Cawagas to return as the editor of the academic-refereed journal. She accepted, serving from 1999 to 2006. During this time, the journal's name was changed to *International Journal of Curriculum and Instruction* (IJCI).

Although the founding name of the association, World Council of Curriculum and Instruction, has been maintained in the title of the official refereed publication, the title has been revisited in consideration of developments in their field. With *instruction* considered pedagogically outdated by many leaders in the field, *teaching-learning* is preferred rather than *instruction*. Although critical thinking, holistic learning, and transformative learning may not be included in the instruction paradigm, articles reflect these critical pedagogies and contribute to professional literature in research and in practice. Themed issues include the following: women and children, *WCCI Forum*, volume 3, issue 2; environmental care, *IJCI*, volume 1, issue 2; and peace education, *IJCI*, volume 2, issue 1.

The North America Chapter also publishes a journal in conjunction with their conferences. Scholars from Australia, Brunei, Canada, China, Cuba, Cyprus, India, Indonesia, Japan, Lithuania, Mexico, New South Wales, Nigeria, Pakistan, Papua New Guinea, the Philippines, South Africa, South Korea, Sri Lanka, Thailand, Tibet, Uganda, the United States of America, and Zambia are among many who have published in the journals of WCCI.

## *KEEPING TRACK*

---

Even in an applied field such as curriculum studies, it is rare for an academic book to attract and influence a broad spectrum of policy makers, practitioners, and everyday people. Jeannie Oakes's *Keeping Track* is an exception. The book, first published in 1985, draws upon the results of a large national study to describe the effects of grouping, or tracking, students by perceived ability. Although it was not the first scholarly critique of tracking, its combination of accessible writing and compelling evidence helped spark national debate about a practice that had become pervasive in U.S. schools. A second edition issued in 2005 contains a new preface plus two additional chapters that analyze this debate and the detracking movement it spawned.

Oakes opens her book by defining tracking as a subjective process by which students are sorted into high- and low-level courses that offer very different educational opportunities. She then summarizes the misconceptions that she believes underlie this practice: that students learn more in homogeneous groups, that tracking protects the self-esteem of "slower" students, that track placements are appropriate and fair, and that teaching is harder in heterogeneous classes. In the following chapter, she traces tracking's historical roots to the early 20th century when immigration fueled unprecedented increases in secondary school enrollment. Tracking was grounded in racist, classist, and paternalistic beliefs about these immigrants and others. The

practice was embraced as an efficient scientific method to provide this newly heterogeneous student body with schooling appropriate to everyone's academic capacity and future station in life.

The six chapters that comprise the heart of the book describe tracking-related findings from *A Study of Schooling*, led by John Goodlad. This massive 1970s study involved 25 geographically and demographically diverse secondary schools, 297 classrooms, and hundreds of hours and observations and interviews. (The same study was the subject of Goodlad's classic book, *A Place Called School*.) The results, as described by Oakes, are a damning indictment of tracking. Low-track students do not just move slower, they learn less. Their inferior curriculum consists largely of learning and relearning basic skills. Teachers are tracked too, with the best instructors reserved for the higher tracks. Low-track teachers are more punitive and spend more time on discipline. In turn, low-track students develop negative attitudes and behaviors. They argue, act up, and perceive their teachers and peers as unfriendly and unkind. By contrast, the students in the untracked classes included in the study absorbed rigorous material in a supportive environment indistinguishable from what was found in higher tracks.

Oakes accordingly fails to find tracking to be equitable or fair because students who need the most are getting less. And decisions about who gets what are tainted by subjective judgments that disadvantage low-income students of color. Oakes raises constitutional questions about the degree to which tracking violates students' rights to due

process and equal protection under the law. Drawing upon the reproductionist theory of Samuel Bowles and Hebert Gintis, she concludes that tracking legitimizes inequality by providing an illusion of meritocracy. She concludes by recommending that schools eliminate tracking.

In the years that followed the publication of the first edition, tracking was denounced by a diverse group of organizations including the National Governors Association, the state of Alabama, and the National Education Association. Yet the majority of U.S. schools continue to track. In the chapters new to the book's second edition, Oakes provides some reasons why. According to Oakes, tracking advocates have mischaracterized tracking research as inconclusive, erroneously insisted that tracking has changed so dramatically in the past 20 years that it is no longer problematic, and argued that tracking should simply be fixed since detracking would be even worse. In addition, educators fear that detracking will cause "bright" students to flee. Supporters of tracking tend to be more vocal than detractors. Administrators shrink from the parental dissatisfaction that may result from school reform.

Still, Oakes remains optimistic, presenting case studies to demonstrate how detracking can be accomplished. Such optimism is especially noteworthy given Oakes's views that detracking itself is little more than a first step. In Oakes's eyes, schools will not truly change until detracking is accompanied by deeper political and normative paradigm shifts.

## KILPATRICK, WILLIAM HEARD

---

William Heard Kilpatrick (1871–1965) popularized the project method and child-centered curriculum and proved most important to curriculum studies as an emblematic figure for progressive education curricula. Although Kilpatrick's reputation suffers criticism for misapplying progressive ideals and the beliefs of John Dewey, he remains the self-proclaimed interpreter and leading proponent of the progressive education curriculum of the early to mid-20th century.

Kilpatrick graduated from Mercer College and taught mathematics in the Georgia public schools, returning to Mercer to serve as a faculty member and acting president. His decision to leave Mercer was precipitated by charges of religious heresy, where he subsequently moved to Teachers College and completed his PhD in 1912. Referred to during his later years as the white-haired gentleman from Georgia with his distinctive appearance and accent and charismatic public presence, Kilpatrick taught at Teachers College from 1912 until his retirement in 1937. He was described by the New York City press as Teachers College's million dollar professor in recognition of his large classes and the amount of tuition he generated for the institution.

The launching of Kilpatrick's national career occurred in 1918 with the publication in *Teachers College Record* of "The Project Method: The Use of the Purposeful Act in the Educative Process," later reprinted and widely distributed in monograph form. Although the project method was already popular in the areas of agricultural, architectural, and vocational education, Kilpatrick offered the general elementary school classroom teacher a rationale for shifting the curriculum away from rigid content and recitation to a more child-centered program. With the emergence of new psychological and sociological research influencing educational thought, Kilpatrick focused curriculum planning on the interests of the self-directed student. Curriculum development, thus, turned from predefined subject matter to experiences that fostered self-directed, purposive living. Accordingly, curriculum was viewed as a process of living in what has become a fundamental definition for the field of curriculum studies. Yet such basic beliefs, willingly embraced by progressive educators, still

left teachers wondering just what to do in the classroom, and the project method offered tangible direction and guidance for developing a child-centered program. Kilpatrick classified types of projects and described the project method as having two necessary components: (1) a hearty, purposeful act and (2) an activity conducted in a social context. From this framework of curriculum and instruction, Kilpatrick popularized this educational method that came into common usage throughout the 20th century. Although the practice received much criticism from both progressives and traditional educators, Kilpatrick underscored the importance of subject matter, the role of teacher as expert and guide, and the significance of democracy as a social process for schools. The project method remains the most popular and defining curricular-instructional practice of progressive education.

Interestingly, one of Kilpatrick's truly insightful contributions to curriculum studies never received the attention that many believed it deserved: the concept of concomitant learnings. Although Kilpatrick saw the project method as providing a framework for curriculum design and development, his belief in educating the whole child and his familiarity with learning theory caused him to take a broader view of educational experience. He would come to articulate two types of learning: (1) direct (or primary-intentional) learning resulting from traditional or student-centered curriculum and (2) concomitant (or associate-simultaneous) learning, representing students' transactional feelings, attitudes, and reactions to content (again, stemming from primarily the project method, but also possible in traditional school settings). Concomitant learning recognized positive and negative aspects of the process of learning, including both the joy of discovery and the dread of testing. Thus, Kilpatrick's conception of curriculum as the process of living caused the fostering of positive attitudes and habits toward learning, through concomitant learning, to become as important a curricular activity as the actual selection of the content. The project method—arising from the interests of the child and engaged as a hearty, purposeful act—served as a successful means of providing both direct and concomitant learning. Since Kilpatrick underscored the importance of concomitant learning and student growth and interests, critics of progressive education were once again able to interpret

his comments as a way to expose an inattention to subject matter and disciplinary knowledge.

In addition to his contributions to curriculum design and development, Kilpatrick helped to initiate many educational and social projects of importance to the field of curriculum studies, including the John Dewey Society and its yearbooks that often addressed curriculum issues, Bennington College as an example of progressive education curricula at the postsecondary level, the Bureau for Intercultural Education, and the *Social Frontier*. Further, Kilpatrick assisted indirectly generations of textbook authors by serving as the model, an exemplar, for their descriptions of progressivism. Gladly branding himself as the leading disciple of John Dewey, Kilpatrick served elementary teachers of the 1920s and 1930s by providing a specific, tangible curricular-instructional method that could be immediately applied to classroom practice and later, served as a charismatic spokesperson—a teacher and public figure—who could represent progressive education to educators throughout the country and world.

## KLIEBARD, HERBERT M.

---

Over the course of four decades, Herbert M. Kliebard (1930– ) has been one of the leading

U.S. curriculum theorists and historians, influencing countless scholars, administrators, and teachers who took his classes and read his many publications. As a faculty member at the University of Wisconsin at Madison from 1963 through 1999, he taught several thousand students who learned, for example, that curriculum planning could be approached in other than an overly technocratic and rational way, indeed as an area of thoughtful and creative deliberation and decision making concerning interrelated issues of purpose, selection, organization, assessment, culture, and politics. He has also shared his historical and theoretical insights in close to 100 journal articles, book chapters, and reviews, some of which have become classics in the curriculum literature, such as several that first appeared between 1968 and 1977 and have been reprinted many times: "The Curriculum Field in Retrospect," "The Tyler Rationale," "The Rise of Scientific Curriculum-Making and Its Aftermath," and "Curriculum Theory: Give Me a 'For Instance.'" Kliebard has also published eight books: *The Language of the Classroom* (coauthored); *Religion and Education in America: A Documentary History*; *Teacher, Student, and Society: Perspectives on Education* (coedited); *Curriculum and Evaluation* (coedited); *The Struggle for the American Curriculum, 1893–1958* (three editions); *Forging the American Curriculum: Essays in Curriculum History and Theory*; *Schooled to Work: Vocationalism and the American Curriculum, 1876–1946*; and *Changing Course: American Curriculum Reform in the Twentieth Century*. It would be incorrect to say that anyone invents a field of study, but Kliebard has certainly been one of the most influential contributors to the historical study of the U.S. curriculum, to the idea that in order to understand complex curricular and other school phenomena, one must go back to its genesis.

Kliebard was born and raised in New York City, graduating with an AB in English in 1952 and a MA in 1953, both degrees from City College of New York. After working for 1 year as an English teacher at Bronx Vocational High School (the school that formed the basis for the *Blackboard Jungle* novel and movie), he served in the U.S. Army Medical Corps for 2 years before returning to his previous high school position. From 1956 to 1962, he worked as a reading specialist for the

Nyack, New York, Public Schools and then served 1 year as a research associate at Teachers College, Columbia University. By this time, he had begun his doctoral studies in reading at Teachers College, but switched his major to curriculum and teaching, working closely with Arno Bellack. He earned his doctorate in 1963 and joined the faculty at the University of Wisconsin at Madison, teaching in the departments of curriculum and instruction and educational policy studies until his retirement in 1999 (having attained full professor rank in 1970). Kliebard has received many professional honors, including a distinguished faculty award from the University of Wisconsin, a distinguished alumnus award from Teachers College, the Outstanding Achievement Award of the John Dewey Society, and a lifetime achievement award from the Curriculum Studies division of the American Educational Research Association.

After initial work in analyzing teachers' classroom discourse, Kliebard embarked on an intellectual journey of what he early on referred to as examining more closely the field of curriculum's persistence and perplexing questions and issues. During his long and prolific career, he has engaged in the historical study of a wide range of topics that intersect with the selection, organization, and evaluation of the curriculum, in doing so revealing how democracy, status politics, symbolic meanings, liberal education, science, vocationalism, differentiation, social control, and institutional change, for example, are intertwined with curriculum work. Influenced in particular by the work of John Dewey, Boyd Bode, and Edward Krug, Kliebard adopts the kind of critical perspective, along with a commitment to meticulous research and an appreciation for nuance, that is needed to question and redefine the taken-for-granted assumptions of the field. He highlights the myriad ways in which the celebratory, overly simplified, and consensual accounts of many curricular scholars and practitioners do not provide the conceptual frameworks to make sense of what has occurred and why. Indeed, to understand specific practices and policies of the schools today, and in particular their instructional programs (involving, e.g., planning, standards, tracking, integrated curriculum, and assessment), one needs to reach back to the past and closely examine the evolution of the professional field. A historical perspective is

particularly important when one sets out to improve the curriculum, for example, to address the changes of the 21st century.

In his pathbreaking and oft-cited book, *The Struggle for the American Curriculum, 1893–1958*, Kliebard makes this point abundantly clear to new generations of prospective and current educators. The role of social efficiency educators, as well as humanists, developmentalists, social meliorists, and others with strong ideological convictions about what should be taught to whom and how it should be organized and evaluated, may not be overtly referred to in the classrooms and hallways of our current schools, but their strong influence can most certainly still be felt. Kliebard has provided richly detailed accounts that substantiate his critical insight that the curriculum was and continues to be a battleground for strongly held, competing values, politics, and status aspirations. Anyone seeking to gain an essential understanding of the curriculum field, in particular its searing conflicts

and untidy compromises, would benefit from starting with his work.

## LACANIAN THOUGHT

---

Lacanian thought refers to the work of French psychoanalyst and poststructuralist Jacques Lacan (1901–1981). In curriculum studies, his ideas are used to explore desire in the classroom, challenge the belief that identity is a fixed concept, and examine the subject’s relationship with language. His writings and lectures are collected in *Écrits*, published in 1966, and in several volumes that contain his seminars delivered between 1953 and 1981. The three orders of the Lacanian self—the imaginary, the symbolic, and the real—were influenced in part by psychoanalyst Sigmund Freud, structuralist Ferdinand de Saussure, and surrealist Salvador Dali.

The imaginary refers to a phase before the acquisition of language and therefore of an identity separate from a caretaker. Subjects are defined through an imagined sense of self based upon what they see constructed through the gaze of another. Lacan’s interpretation of the mirror stage (first presented at a conference in 1936) refers to the time when infants between the ages of 6 and 18 months observe themselves in the reflection of another or an Other (i.e., mirror, mother, or sibling). Recognizing for the first time an external, cohesive identity, subjects seek to regain that ideal sense of wholeness. However, because that identity or image changes with each new reflective surface, the subject can never regain a stable, fixed identity, but continues to seek the comfort of one.

Therefore, subjects must adopt the rules and language of the symbolic order. Lacan and many of those who use his theories call their participants subjects because they must succumb to language to express themselves. As they seek their unconscious needs and desires, subjects must succumb to the symbolic register that is governed by the laws of language, which is controlled by the paternal. Furthermore, because they possess a phallus, male subjects are able to employ the symbolic order, whereas females are forever situated outside that order.

The real is the opposite of the imaginary and exists outside the symbolic. This order represents that which always remains, but is forever unattainable. Once a subject uses the symbolic (i.e., language) to try to define that which is impossible to define, it is no longer real, but is constructed by a subject. In other words, the real is always in its place, and (and to refer to one of Lacan’s tenets) because the unconscious is structured like a language, it is impossible to access that which cannot be expressed through the symbolic.

Feminist and queer theories build upon and challenge many of Lacan’s concepts. Luce Irigaray, Hélène Cixous, and Julia Kristeva each question the notion that the female cannot express herself through language because it is inherently male. Irigaray posits that the female, therefore, is a male construct, while Cixous advocates that the female does indeed possess a language of her own. Kristeva rejects the idea that the subject must suppress the feminine during the mirror stage and argues that the feminine expresses itself through

the pulsations and rhythms found in language. In her work on performativity, Judith Butler addresses Lacan's ideas that subjects experience lack because they desire the phallus. Agreeing with Lacan's explanation of the phallus as a signifier, not always synonymous with penis, Butler argues that women can both possess and lack the phallus through performance, for example, by dressing in drag or by displacing the penis as signifier by substituting another body part.

In curriculum studies, Lacanian thought is used to explore the complex relationships between teachers and students, to explore how language fails to convey the real and how the desire for the real may be transferred to the Other, and to explore the ethical questions that might result from these interactions. For example, a student who desires the affections of a teacher might in actuality covet the power a teacher represents. The student might transfer that desire onto the teacher in an effort to possess the unimaginable. In other words, employing Lacan's theories to read this situation would reveal that this student or subject might lack or desire power. Once this identification is made, however, the subject cannot signify that lack through language and will still experience lack. Lacanian thought brings to curriculum studies ideas grounded in psychoanalysis, post-structuralism, and surrealist art.

preparation of pre- and inservice PreK–8 educators for engaging children and youth with the subject matter, pedagogical practices, and current debates related to the commonly accepted strands of language arts, which include reading, writing, speaking, listening, viewing, and visual representation. This topic is relevant to the field of curriculum studies because the language arts remain the most foundational—and potentially most controversial—of curricular emphases addressed within any PreK–8 school setting. This encyclopedia entry provides a definition of English language arts education curricula, including an overview of their most commonly recognized elements; brief discussions of the primary assumptions, theories, and curricular standards associated with this element of curriculum; cursory examinations of historical and recent debates and controversies related to this field of curriculum studies; and descriptions of examples of four of the key strands included in language arts education curricula.

#### Definition

Although language arts education might be taught with a focus on any language (e.g., Spanish language arts education or Chinese language arts education), in the United States it is assumed that one is considering the English language when speaking of a language arts education curriculum. Of course, in the United States—with an increasingly diverse population, including higher percentages of non-native English speakers—traditional language arts education curricula frequently include considerations of the needs, abilities, and skills related to other languages.

Language arts education curricula are generally differentiated from English education curricula by both the grade levels toward which these subject matters are oriented and the range of subtopics that are included in each. The language arts are generally organized as discrete courses of study taught in elementary through middle or junior high school (PreK–8) grades; these courses are distinct from English courses (generally taught in high school settings) in that language arts curricula include a holistic integration of all of the elements listed above (i.e., reading, writing, speaking, listening, viewing, and visual representation), of which two are written, two are visual, and two are oral.

---

## LANGUAGE ARTS EDUCATION CURRICULUM

---

Language arts education curricula are the sets of materials and practices generally used in the

In addition, in the grades in which the language arts are taught, it is commonly recognized that these topics and skills are integrated within and across subjects (e.g., science or social studies), even if these are also taught as discrete courses. As students progress to high school, these integrated language arts are isolated into distinct courses and curricula, each of which might focus remotely on literature, composition, speech, debate, drama, video, multimedia, or related courses.

### Assumptions, Theories, and Standards

Several assumptions and theories lie at the heart of the nature of language arts education curricula. These include the belief that the upper elementary and middle school (Grades 4–8) youth who are the primary audiences for language arts curricula are developmentally unique and benefit from an integrative approach to curricula and teaching practices. As with many fields of curriculum, the features of language arts education curricula are the outgrowth of a set of psychological characteristics believed to be most prevalent among upper elementary and middle school children.

Psychological, constructivist, sociolinguistic, and sociocultural perspectives on how children learn illustrate how students' knowledge is organized in the brain. Jean Piaget and Lev Vygotsky both describe cognitive structures that suggest that the organization of children's brains becomes more integrated as their knowledge grows. Accommodation and assimilation are the primary cognitive processes at work: Accommodation takes place when learners' existing mental frames—or schemes—are modified by new information that they encounter, and assimilation occurs when new information is incorporated into children's existing schemes. All people attempt to achieve and maintain equilibrium—to make sense of new information that they encounter; naturally, children in school encounter new information on a regular basis, but teachers must be conscious of the quantity and quality of this information, seeking to share what Piaget calls moderately novel facts, data, and concepts. Language arts education curricula attempt to appeal to early adolescents' developmental needs for integrated, but increasingly discrete, curricular topics.

Language arts education curricula are also rooted in now commonly accepted prescriptive

principles or content standards. The standards movement has greatly altered the curriculum landscape in the past decade, with states generally developing their own standards and designing their own or adopting commercially available forms of curricula for language arts instruction. The majority of these standards are closely related to those developed by the National Council of Teachers of English (NCTE) and the International Reading Association (IRA), which combined are the two primary professional organizations serving language arts educators. While the standards are not in and of themselves language arts education curricula, they are considered near absolute guides for the selection and development of such curricula.

### Debates and Controversies

Two controversies are particularly important to consider in any discussion of language arts education curricula. The first relates to what has become an almost accepted fissure between the curricula language arts teachers actually use in their PreK–8 classrooms and the curricula that are presented in language arts education courses. A seemingly insurmountable tension remains between language arts curricula—what classroom teachers actually teach—and the curriculum of language arts education programs, which are typically university-based and include a wider array of theoretical perspectives and broader consideration of a variety of media.

The second controversy is the result of the increasing diversity (particularly in terms of language) of the U.S. school population and the persistent achievement gap between children from higher socioeconomic families and those students from more economically, racially, and ethnically diverse settings. It is arguable that as the United States has become more diverse linguistically and culturally that teachers are facing additional challenges in teaching the English language arts. Increasing percentages of students who are non-native English speakers arrive in schools virtually every day, and nondominant and nonstandard language and communication forms are increasingly common among families, communities, and youth who were either not born into or are not successful participants in the primary economy. As a result, effective language arts teachers must be increasingly culturally sensitive and competent,

with abilities to appreciate, study, and honor their students' given relationships to and skills with these school-based reading, writing, speaking, listening, viewing, and visual representation tasks. Given these daily challenges to effective language arts instruction, teachers must be conscious of how their beliefs about how, why, and what children learn impact their daily practices.

The gap between language arts education curricula (those materials and practices used in the training of PreK–8 language arts teachers) and language arts curricula (those materials and practices actually used by PreK–8 teachers in their school settings) is perhaps most evident when the curricula used to serve the needs of the increasingly diverse U.S. school population are considered. Ostensibly in an effort to most efficiently address the curricular guidelines and achievement objectives to which districts and schools are being held accountable (most often through high-stakes, standardized assessments), many districts have turned to scripted curricula that focus on basic skills that are presented in a virtually teacher-proof fashion. Although these curricula are the centerpiece of an increasing number of districts' language arts programs, such materials rarely have a place in the language arts education curricula to which preservice teachers are introduced.

### Examples of Language Arts Curricula

The richest and most complete examples of language arts education curricula address all six of the commonly accepted strands of the language arts. Experts agree that the most effective language arts teachers integrate instruction in and incorporate opportunities for students to use all six every day in their classroom curricula. Seminal examples of these curricula generally focus in substantial detail on just one or two of these strands; scripted curricula that attempt to address all six strands generally do so in a streamlined, commercially appealing, and cursory fashion. This encyclopedia entry focuses on historically significant examples of curricula that address the strands of reading, writing, viewing, and visual representation; these reading and writing curricula are among the most respected and widely used across the United States, and the viewing and visual representation examples are among the latest trends in curricular reforms.

Nancy Atwell has been among the most important of curriculum theorists and developers who have attempted to consider the integration of the six language arts strands while paying particular attention to the psychological and sociocultural characteristics of middle school-aged youth—for whom such an integration is understood as most necessary. Atwell's *In the Middle: New Understanding About Writing, Reading, and Learning* is widely considered a foundational text for the teaching of reading in language arts classrooms. Among the most commonly accepted curricular forms described by Atwell is the literature circle, a pedagogical approach that allows for the use of a wide array of literature in a language arts classroom, but that provides youth with structures for playing authentic roles and making scaffolded, but self-directed choices in the selection of this literature and the ways in which they engage with it. More recently, Jeff Wilhelm has provided detailed examples of what Gloria Ladson-Billings has described as culturally relevant reading curricula and strategies while explicitly addressing the guiding standards outlined by NCTE and IRA.

Paralleling Atwell's work on reading curricula and instruction is Lucy Calkins's *The Art of Teaching Writing*. Her volume describes elaborate student-centered mechanisms for engaging children and youth with writing activities, focusing on the now commonly accepted structure of the writing workshop. As with Atwell's and Wilhelm's work, Calkins's curriculum theory and development provide not so much explicit examples of required writing activities as much as a general writing instruction orientation that appeals to the psychological traits and stages of development of elementary and middle school-aged youth. More recently, the *6+1 Traits* writing curriculum has been widely adopted by districts and schools across the United States; these materials rely on extensive research into the characteristics of quality writing across genres.

In the past 20 years, the role of technology, visual literacy, viewing, and visual representation as language arts has become much more prominent. These often fall under the more general term of critical literacy, which calls on teachers to honor youths' proficiency with the consumption of visual texts while also providing students with opportunities to manipulate and construct their own versions

of these texts—often with a perspective that critiques the passive consumption of existing visual tools. When the book and other published paper forms were the dominant texts inside and outside of school, it was arguable that PreK–8 language arts curricula and language arts education curricula were reasonably current with these forms. But as video, multimedia productions, and electronic media (including Web-, music-, e-mail-, and mobile phone-based tools and text forms) have proliferated—and as youth culture and its visual orientation have influenced popular culture in an increasing, more fluid, and swift manner—school language arts curricula and language arts education curricula have struggled to remain current.

James Gee, Brian Street, Elizabeth Moje, and Ernest Morrell are among the most recognized of curriculum theorists associated with this movement toward viewing and visual representation as foundational language arts. The Center on Media Literacy, among other organizations and individuals, has developed seminal curricula that allow children and youth not only to interpret visual media, but also to develop their own. Rooted in Paulo Freire’s notion of conscientization, Moje, Morrell, Linda Christenson, and Jessica Singer have articulated critiques of language arts education curricula that do not engage students in these viewing and visual representation activities and have developed substantial examples of curricula that provide youth with opportunities for using these and other strands of the language arts in the pursuit of larger, more real-world and social justice-oriented ends.

## LANGUAGE ARTS EDUCATION CURRICULUM, HISTORY OF

---

History of language arts education curricula refers to historical antecedents and underpinnings that have contributed to the general conception of language arts education curricula. This topic contributes to the larger study of curriculum by illustrating seminal work that formed the foundations for current practices and methodologies in the field of language arts education. This encyclopedia entry includes a brief review of early 20th-century trends in English education, an examination of how social and historical events have encouraged shifts in the perception and implementation of language arts curricula over time, and a subsequent review of how modern perceptions have once again evolved to reflect earlier conceptual notions.

### Early 20th Century Trends

As early as 1917, policy statements and reports issued by the National Council of Teachers of English (NCTE) documented a need to move beyond a departmentalized framework for the teaching of English that prepared students for the eventual meeting of college entrance requirements. Postindustrial advances in science and psychology influenced work in education by encouraging the reenvisioning of the learning process and the learner from a fragmented, behaviorist perspective to a more holistic, whole child appreciation.

Within this context of synthesis, NCTE published its influential 1935 report on the necessity of a correlated curriculum that is also popularly known as an integrated curriculum. The premise of a correlated curriculum is that learning occurs through the varied uses of language and experience across and within interrelated subject areas for a variety of real and relevant purposes and enables the learner and teachers to appreciate patterns: world patterns, subject patterns, experience patterns, and psychological growth patterns. Ultimately, such a curriculum is transformative: The learner prepares not only to adjust to the demands of life, but also to transform or improve the conditions of living.

The correlated English curriculum of this era was organized on a continuum in six forms:

1. The integration of English with other subjects through incidental references and isolated projects
2. An English course based on relationships with other subjects, but not requiring the cooperation or modification of other subject courses
3. The fusion, or blending, of English with another content or subject area
4. The integration of groups of subjects
5. A whole curriculum based on the integration of all subjects
6. A seamless curriculum, or one that does not acknowledge subject area boundaries

Recognizing the strengths and limitations of such English language arts curriculum configurations, educators were encouraged to ask several guiding questions throughout the design process that would ensure the curriculum be balanced, reflect important values, be genuine, be interesting to students, be administratively feasible, be within the range of faculty abilities and knowledge bases, and contain the resources necessary for implementation.

### Events Leading to Language Arts Curriculum Change

As enthusiastic as the progressive voices in education were during the period leading to the early

1950s, the launching of the Russian satellite *Sputnik* in 1957 signaled a rapid reexamination of educational reform in the United States, in particular by critics of progressive education. In an emerging political climate characterized by fear for the U.S. position as a world power, curriculum efforts once again embraced conservative ideologies. Many progressive ideas and efforts were replaced with a renewed focus on the role of technology in education and society and the reestablishment of a separate-subject approach to curriculum. Consequently, widespread attention to curriculum integration during the 1960s and 1970s waned during this period, although school restructuring would eventually rekindle the focus.

Language arts curriculum and practice, given this historical context, reflected a stronger emphasis on a mastery model of learning. Students were frequently permanently grouped, or tracked, by ability level. Student comprehension of reading material was primarily determined through a style of interrogation using low-level questioning techniques that resulted in responses at the most cursory levels of recall and understanding. Assignments and activities also reflected a lack of rigor, requiring learners to practice skills and strategies in heavily structured order and in isolation. Drills involved objective student responses in the form of circling, matching, listing, and otherwise merely identifying correct answers. A pronounced de-emphasis on the individual and the education of the whole child characterized this period as education policy makers struggled to keep the nation competitive with other industrialized countries.

### Revisiting the Origins of Early Language Arts Curriculum

Renewed interest in how children learn through the use of language and in the field of cognitive psychology in general led to a plethora of literacy research in the latter part of the 20th century. The work of pioneers such as Lev Vygotsky and Jean Piaget encouraged language arts curricularists to return to the idea of the literacy development of the whole child in an integrative framework. This movement produced the most commonly supported and research-based practices in contemporary language arts education.

Among the instructional changes that reflect early 20th-century ideas about the correlation of learning English in meaningful ways are a stronger emphasis on the interrelatedness between writing, reading, speaking, and listening across content areas; a greater use of trade books and a variety of print and other media beyond the textbook; an increased attention to the scope of the instructional frame of reference of the learner and learner choices; and an emphasis on the formative nature of assessment and knowledge development. With regard to the social nature of learning, students and teachers seek patterns of meaning collaboratively and cooperatively. Finally, students are encouraged to learn and use language to function not only as productive citizens, but also as individuals who are capable of evaluating, problem solving, and creating innovative, transformative processes.

## LANGUAGE EDUCATION CURRICULUM

---

Language education may be referred to simply as the teaching and learning of language. When one looks beneath the surface, however, the complexities of curriculum for language education become apparent. Language education curriculum may be defined in many ways, from the design, implementation, and assessment of programs to support the acquisition of target languages; to specific

materials, textbooks, exercises, and instructional practices comprising the instructional program; to a conception of language education curriculum that considers purposes and contexts for which language instruction and acquisition are geared and expanded to acknowledge the impact of larger educational and societal influences on individuals involved in the teaching and learning of languages. Examining complexities associated with language education curriculum provides a glimpse of challenges inherent to the field of curriculum studies by highlighting the interaction of influences beyond the classroom that affect the success of school curriculum.

Joseph Schwab's framework of the four commonplaces of curriculum—teacher, learner, subject matter, and milieu—is used in this entry to address and explore the intricacies of developing and implementing language education curriculum in North America.

### Milieu: Context of Developing and Implementing a Language Education Curriculum

To begin with, the commonplace of milieu, or context in which language education curriculum is developed and implemented, needs to be taken into consideration. Shifts in language education curriculum reflect demographic changes in society that include increased numbers of individuals from diverse ethnic backgrounds and a heightened need for the acquisition of language for practical as well as for literary purposes. The world is becoming increasingly diverse as immigration and migration rates grow. Currently, approximately 185 million people around the world live outside their countries of birth. Within this global context, the North American population is becoming increasingly diverse through immigration and the birth of children into immigrant families. Accordingly, there is a growing need for English language education for English language learners (ELLs) to assist them in achieving sufficient fluency to participate in society and to progress through the education system, in addition to the ongoing need for English education for native English speakers to support their development of literacy. Furthermore, in a society that comprises large numbers of immigrant and minority students, language education in terms of

maternal language development and/or maintenance needs to be acknowledged. Finally, awareness of the importance of and need for foreign or second language instruction for all students to facilitate communication in international contexts has become increasingly recognized as international travel and Internet communication have become widespread in recent decades.

Coupled with the pragmatic belief that language education curriculum needs to reflect demographic changes in society is the growing realization of the contested nature of language education in North America. There is a general perception that bilingualism and multilingualism are not as highly valued in North America as they have been in Europe. Some proponents of English-only education in North America claim a mismanagement of limited financial and educational resources as money is earmarked for English as a second language and ELL programs and programs to support the development and maintenance of maternal languages of immigrant and minority language students. At the same time, some researchers claim a denial of linguistic resources that immigrant and minority students bring to North American schools as maternal language proficiency is being overlooked and ignored to the extent of contributing to a squandering of valuable resources.

### **Subject Matter: What to Include in the Curriculum and How to Implement It**

The contested nature of language education curriculum also carries over into its design, implementation, and assessment. In curricular terms, the development of oral and written proficiency in the target language may be considered the subject matter. Decision making about the content and implementation of the subject matter of language education curriculum is plagued by much uncertainty and many questions.

To begin with, goals for language education curriculum need to reflect the purposes for which this education has been identified as being important. If the principal goal of language education is to teach students about technical knowledge about semantics and grammatical functioning of parts of speech in the target language in ways that will enhance their written fluency, activities and lessons in the curriculum will differ significantly

from activities such as class discussions and opportunities for speech or drama activities that would build communicative competence and language awareness for travel or work purposes and confidence in spoken interactions with native speakers of the target language. If it is important that students learn about the culture, societal structure, and mores of the communities of which the target language is part, instructional activities need to support the development of this knowledge. Given the many purposes for which language education may be important to those involved, ambiguity about curricular decisions pertaining to materials, exercises, philosophies, and teaching practices is not surprising.

Research in the areas of applied linguistics, language acquisition, and cultural studies informs our knowledge of pedagogical practices for the development and implementation of language education curriculum. The abundance of approaches and philosophies about how best to accomplish language education curriculum goals, the large body of language education theory, and the differences in professional opinion about the design of language education curriculum and how best to implement ideas and practices further complicate its design and implementation. Descriptions of a few approaches are included in this entry to provide a glimpse of the variety and range that are currently employed. Wallace Lambert and Richard Tucker introduced an immersion model in an attempt to simulate naturalistic settings for language acquisition that resemble circumstances and the level of motivation under which children first acquire their maternal languages. Establishing a need-based context for use of the language and using native language speakers as teachers to model the target language for purposes of communication form the foundation for this method of language instruction. Dual language programs, where language minority students are taught in the home language to support the development of the target language, and bilingual programs, where instruction is conducted in both the majority and the home language with the goal of bilingualism in both languages, differ significantly from previously existing language programs in the amount and extent of exposure to content-relevant vocabulary and in opportunities for exposure to and use of the language for communicative purposes.

### **Learner: Students Who Language Education Is For**

The success of language education curriculum is shaped significantly by the extent to which the curriculum meets the needs of the students involved. Meeting language education curriculum needs is a challenge due to the wide range of needs and goals of the student population. Prior language education experience, materials, instructional practices, personal preferences, and a rich and varied program of instruction all need to be geared toward the cognitive learning styles and objectives of the students.

With an increasingly diverse student population, researchers and educators argue for language education that includes teaching practices and materials to support their ability to integrate into society. When the curriculum does not draw on the linguistic and cultural knowledge that immigrant and minority students bring to school, their academic success and subsequent career success is jeopardized. Not only are immigrant and minority students likely to feel that they do not have a sense of belonging when their maternal languages and cultures are not acknowledged in their school contexts, but also their exclusion is believed to contribute to the loss of maternal language proficiency of students and subsequent difficulties in communicating with parents, family members, and other members of ethnic minority communities who are not fluent in English. Teachers who advise parents to speak to their children in English as a means of accelerating the children's English acquisition may inadvertently contribute to difficulties in communication between children and their parents. Parents, in effect, may lose the ability to communicate with, guide, and teach their children. Researchers elaborate upon the detrimental personal and familial effects of maternal language loss, and educators advocate for the acknowledgment of ethnic and linguistic knowledge of minority students in the school curriculum to affirm diversity in school. They call for the development rather than the denial of these linguistic resources, and an enhanced awareness of theories, such as the linguistic interdependence principle whereby transfer of knowledge about language structures and components in one language, namely, the maternal language, supports the development of another—the target—language.

The lack of acknowledgment of home cultures has been identified as contributing to the high dropout rate among minority students.

Although instructional issues for students learning a foreign language for professional or personal reasons may be similar to those of immigrant and minority students, they have the advantage of existing fluency in the language of the society. Language education for this population is additive, rather than subtractive, in that foreign language proficiency gained through language instruction is in addition to existing English language proficiency. For immigrant and minority students, however, the acquisition of English is unfortunately associated with loss of fluency in the maternal language due to limited opportunities for practice, few individuals with whom to use the language, and a sense of alienation from ethnic communities where the maternal languages are spoken. ELL students often associate English acquisition as critical to acceptance by English-speaking peers, while maternal language proficiency is viewed as a hindrance to participation in peer groups and associated with rejection or exclusion from desirable peer activities. Not surprisingly, given these circumstances, immigrant and minority students are often eager to acquire English even at the expense of maternal language fluency. ELL students may fail to recognize the personal and academic advantages of maternal language proficiency.

Examination of the relationship between curriculum, schooling, languages, and cultures highlights the role of school in supporting maternal language maintenance. Language, culture, identity, and power are intertwined, and immigrant and minority students are more likely to succeed in school when they are not alienated from their cultural values. A nurturing school environment with a culturally sensitive curriculum that validates linguistic and cultural diversity contributes to the confidence and subsequent academic success of immigrant and minority students and to the overall learning of all students.

### **Teacher Experiences of Designing a Language Education Curriculum**

Although there is general awareness of the importance of accommodating for learning styles and linguistic backgrounds of students, there is

uncertainty about how best to acknowledge the wide range of needs represented in student populations.

Teachers play a significant role in shaping a school community where diverse languages and cultures are represented. Incorporating students' linguistic and cultural knowledge in the school curriculum and supporting the development and maintenance of maternal language fluency help create a school environment where students are proud of their home languages and cultures and feel a sense of belonging in their school. To achieve this, teachers may engage parents and children in discussion of values, rituals, and cultural experiences through family stories, using an integrated classroom curriculum that fosters a sense of community within the classroom while at the same time drawing on the linguistic and cultural knowledge of the families of the students. School-based bilingual literacy projects where parents work with teachers to engage students in writing and reading have resulted in enhanced appreciation of literacy in both English and home languages of students.

Although many aspects of language education curriculum presented here are relevant regardless of the age of the learners, it is important for teachers to acknowledge student age in developing and implementing curriculum. Curriculum for adult learners is inherently different from that for children by nature of the reasons for which language education is sought; their level of motivation to acquire the curriculum content, whether for professional or personal purposes, such as self-improvement, communication with desirable others, or travel; and the contexts in which students are learning the language. Students' prior experiences of schooling, whether in North America or in a foreign country, whether positive or negative, enriching or demoralizing, also need to be taken into consideration.

A final factor to be addressed in this entry is the certification of teachers in the area of language education. Although a significant proportion of teachers in North American school systems have teacher education and certification, language instructors are among a pocket of teaching professionals with lower proportions of certified teachers. This shortage may be attributed to poor or insufficient language instruction during their own schooling, the need for more teachers in certain target languages than are available, or the qualification

process required for the instruction of foreign languages. The shortage of certified language teachers may also be attributed to the additional level of qualification required; not only do language teachers need certification, but they also need to have achieved a high level of proficiency in the target language. The unavailability of advanced instruction in specific target languages in North America, a reflection of the low numbers of speakers in some ethnic communities, may limit opportunities for developing high levels of fluency.

### Research

Many factors need to be taken into consideration in the development and implementation of a language education curriculum. Conceptions of language education curriculum reflect societal, political, individual, and education influences, many of which are highly contested. Ongoing research informs educators, policy makers, and the public about the challenges associated with language education curriculum. Research has been invaluable in acknowledging the linguistic resources and cultural knowledge that students of diverse backgrounds bring to a school context and in informing the work of educators as they develop language education curriculum. Despite an increasing body of literature, there remains much we do not yet know about language education curriculum.

## LANGUAGE EDUCATION CURRICULUM, HISTORY OF

---

The history of language education curriculum is highly complex and reflects the contested nature of language education curriculum that is strongly influenced by political, social, educational, and demographic influences. Rather than attempting to cover language education curriculum in English education as well as in the instruction of second or foreign languages in this entry, the focus is on language education curriculum for the instruction of second or foreign languages as preparation for participation in society.

### Societal Context of Language Education Curriculum

Education in North America has a long history of focusing on English as the language of instruction and communication in schools. Despite an increasingly diverse population with larger numbers of

students speaking non-English languages, English remains the standard language of instruction and communication in North America. The use of other languages was often ignored, commonly discouraged, and sometimes even punished in school contexts as a means of accelerating English language acquisition. These practices reflected commonly held beliefs that adherence to home languages and cultures was detrimental to the development of English language proficiency in immigrant and minority students.

Sink-or-swim approaches to English language instruction for immigrant and minority students, whereby students were expected to complete academic activities alongside native English-speaking classmates without the benefit of instructional support, were commonly accepted during the middle decades of the past century, although gradual and more deliberate instruction to support the nuances of English language acquisition were more widely accepted, and even expected, during later decades. Philosophies of language learning have shifted from a perception that minority students should be expected to participate, and succeed, in existing curriculum developed for mainstream, English-speaking students, to a perception that immigrant and minority students need specialized curriculum to support their acquisition of English and adaptation to North American schooling.

Difficulties of implementing language education curriculum in North America are further exacerbated by a lack of acknowledgment for the value of bilingualism and/or multiculturalism in society. Although European countries have long held general acceptance of the advantages of and possibilities for bilingualism and multilingualism due to their proximity to neighboring countries and the relative ease of travel across national borders, North American societies have held less acceptance toward possibilities for proficiency in multiple languages, opting instead for a focus on English. This trend is especially pronounced in the United States. Canada, while heavily influenced by its historic connection to Britain, has been more open to bilingualism, with its official bilingualism policies, despite the long-standing animosity between some French Canadians in the French-speaking province of Québec and inhabitants of other, English-speaking provinces. Regardless of these tensions, this political context has enabled and supported

the development of language immersion as a viable option for second language acquisition to a relatively high level of fluency for students.

### Language Education Programs

Earlier language education was heavily influenced by models of instruction based on memorization of grammatical rules and acquisition of semantic, lexical, phonological, and discourse knowledge and less time devoted to the development of sociolinguistic skills including oral competency or the provision of opportunities to use the target language in authentic situations. More recently, there has been a shift to models of language instruction that include an emphasis on language acquisition for communication in professional and personal situations. With the increasingly diverse population that accompanied increased immigration from non-English speaking countries, a shift in the availability of language programs to reflect this demographic change became necessary.

Immersion education that began with Wallace Lambert and Richard Tucker in Montreal, Canada, is considered among the language education successes in North America. French immersion, whereby students are immersed in French as a means of communication and instruction in their regular school program, has been found to be a more effective means of language education than existing programs where students received approximately 45 minutes of instruction several times a week. This immersion model paved the road for immersion programs in other languages to reflect the ethnic composition of local communities. Currently, immersion programs in languages such as Mandarin Chinese, Japanese, and Ukrainian are available in provinces in Western Canada.

In the United States, variations of immersion programs are used in the language education of immigrant and minority students. Dual language programs are intended as a means for language minority students to learn English while using their home language to support English development. Bilingual programs provide language minority as well as language majority students the opportunity to learn and to develop both languages with the goal of bilingualism. Language education for language minority students in the United States continues to be controversial, and bilingual programs

seem to have more public support than dual language programs. Sheltered instruction programs, usually conducted in pull-out or in-class support by an instructor who accompanies the students to their mainstream classes, provide language minority students with English language support in content areas to ease their transition into regular academic programs. Changes in Teachers of English to Speakers of Other Languages' standards for English language learners reflect a recent shift toward English language acquisition in the context of content area learning rather than the earlier focus on the development of English language proficiency prior to transition into content area classes. Heritage language programs to support maternal language development and maintenance are usually considered extracurricular, often occurring outside regular academic school programs. The design and implementation of this curriculum often reflect cultural influences and methods commonly used in the home country and by the teachers who implement the programs.

## LATIN AMERICAN CURRICULUM STUDIES

---

This entry focuses on the main characteristics that approximate the productions of the curriculum

field of Latin American countries, as well as some aspects that separate them, with special emphasis on the production of the more consolidated countries.

One of the difficulties of tracing an outline of the curriculum field in this region derives from the fact that it has been marked, since the 1990s, by a useful, but at times disquiet hybridism of theoretical perspectives. It is enormously difficult to define the field, and it is impossible to do so on the basis of epistemological questions. There is the possibility of working with Pierre Bourdieu's concept of intellectual field—that is, a space in which different social actors, holders of certain social and cultural capitals in the area, legitimate determined conceptions about the theory of curriculum and dispute between them the power of defining who has authority in the area. In that sense, the field produces theories about curriculum, the objectified cultural capital of the field, which are legitimated as such in competitive struggles fought at different institutionalized levels. Hence, in order to analyze the production of this field, it is necessary to objectify the knowledge produced by the subjects who are invested with the legitimacy to speak about curricula. This legitimacy is conferred by their presence in institutionalized venues.

In view of the option to treat the curriculum as a field, it is important to point out, regarding Latin America, its minor institutionalization. In the great majority of the countries, there are few journals, research associations, and even graduate programs that deal specifically with the subject. As for the latter two, for example, the evaluation and development systems are recent: In Brazil, they were instituted in 1975; whereas in Mexico and Argentina, they date from the 1990s. And it is in those countries that, in past decades, the curriculum field has broadened consistently.

Some general movements of the field are occurring in Latin America, particularly due to international policies directed to it. Although experienced in a different way, the military dictatorships were, between the decades of 1960 and 1980, the political reality of different Latin American countries. The rightist governments and the dictatorships were maintained with strong U.S. support and materialized in the educational field by interventions sustained by international agencies or by aid programs, such as the Alliance for Progress. Those

interventions created real conditions for academic faculties to study in the United States and also allowed for the translation of countless works into Spanish and Portuguese. Thus, the influence of U.S. literature in the curriculum field was very strong in the different countries. The most important reference was, without doubt, Ralph Tyler, but also Hilda Taba, Robert Mager, Benjamin Bloom, and William J. Popham had influence. Also, the curricular projects captained by Jerome Bruner were the subject of transfers guaranteed by official financing. With the end of the dictatorships, in the majority of countries in the 1980s, neo-Marxist literature may have gained prominence in education and in the curriculum field. Nevertheless, echoes of Tylerian rationality continued to be felt in different ways in the various countries.

The end of the dictatorships brought the need to create another educational project, placing the curriculum in the center of the stage. Centralized curricular proposals, whether national or regional, were constructed in the great majority of the countries as they were from the 1990s. That movement broadened the discussion on curriculum, helping to consolidate the field in many countries. In some, such as in Argentina and in Chile, the theorists of a still incipient field took up standpoints with ministries and began to conduct reforms. In others, such as in Brazil, critics dominated the theoretical production scenario of the field. Although with pronounced differences, again, the action of international agencies—especially the World Bank, with its documents for education in Latin America—brought the reforms closer and regulated some common agendas in the theoretical discussions of the field. Thus, curriculum, evaluation, and teacher training were the central features of almost all the proposed reforms. Other approximations can also be credited to the presence of the Spaniard Cesar Coll, one of those responsible for Spain's national curriculum, in teams that worked on the proposition of curriculums in the region. In that way, the wide majority of the reforms were organized around competencies necessary for citizen training and for economic competitiveness. They incorporated transdisciplinary contents and the taxonomy proposed by Coll that classifies the contents into conceptual, procedural, and attitudinal. Because of the prominent role they had in the reforms, those topics began to be

discussed theoretically from the 1990s with greater or lesser centrality, considering the different ways of approximation between the academic field and the policy formulating context.

It is interesting to note that the approximations between the curriculum field in the different countries did not result throughout their history in any identity shared by something as Latin America. In the examples we are mentioning, global movements of control of central countries over the periphery are conspicuous. We maintain, therefore, that there is no articulation that allows us to talk about a production of Latin American knowledge: The countries have different historical processes, in some cases different languages, and political, cultural, and socioeconomic developments with differences that are sufficiently significant to also result in hybrid productions that draw close to as much as separate from each other. If there are global processes like those we mention, postcolonial studies have emphasized how globalization refers as much to the intensity as to the extent of the international interactions, but does not establish the means by which those interactions take place or even how an interaction acquires meaning in some contexts and not in others. A common repertory of significant that is introduced into the disputes in the signification processes does not generate the same circulation of meanings. There is a need to understand the globalization as vernacular, being capable of producing distinct effects mediated as much by the state apparatus as by localization in the context of the practice of schools.

To exemplify the circulation of meanings that occurs in the curriculum field in Latin America, we are mentioning three countries: Brazil, Mexico, and Argentina. These countries have the most consolidated curriculum field, especially due to the greater institutionalization of research in education.

### Brazil

The neo-Marxist schools of thought held clear supremacy during Brazil's redemocratization in the 1980s. Critical sociology that was to substitute instrumental emphasis was also referred to by U.S. authors such as Michael Apple and Henry Giroux and English authors associated to the New Sociology of Education (NSE). Also, French

literature had some presence in the field, especially discussions about everyday life—with references to Bourdieu and Henri Léfèbvre—and about complexity based on Jacques Ardoino.

If that could be the outline of the theoretical configuration of the field, with strong foreign influence, the curricular reforms seemed much more associated with Brazilian Marxist-inspired theorizations. The debate revolved around the thinking of Paulo Freire and of the sharp criticism made by critical-historical pedagogy. That discussion, however, did not arise much at the theoretical discussion about curriculum, where the more heated debate seemed to refer to the adequacy or not of national curriculums.

By the mid-1990s, the field underwent, from the theoretical point of view, a very radical change with the introduction into the Brazilian curriculum field of poststructuralist and postmodern discussions with great editorial impact. Initially, authors were mentioned who sought to articulate modern thinking and its preoccupation with emancipation, for example, and postmodern discussions, whereas in the second half of the decade, more radically poststructural curricular discussions became the texts read in the field. However, critical theory was still the main reference of the works defended in theses and dissertations in the graduate programs.

Curriculum groups were formed in the last decade with researches centered in the everyday school life category. It maintains that the teachers produce curricular alternatives in their everyday networks of tasks and powers, mainly dialoguing with Michel de Certeau and defending a rhizomatic conception of knowledge. In the discussion of curricular policies, they emphasize micropowers and the contingent articulations of minority groups for what is considered valid also from the contribution of the Portuguese sociologist Boaventura de Souza Santos.

Another important group was articulated around questions about knowledge, originating from the preoccupations of the English NSE with strong emphasis on the history of the curriculum and on curricular thought. That group was initially preoccupied with the constitution of school subjects, addressing epistemological, sociological, and socio-historical aspects. Besides the NSE, it was influenced by the work of Ivor Goodson on the history of

school subjects (HSS) and the poststructural approach of Thomas Popkewitz. Those influences express a sliding between modernity and postmodernity that characterized the group. In addition to the recent HSS, the group dedicated itself in the 1990s to studying Brazilian curricular thought, seeking to reconstruct the educational transference category so as to deal with contemporary complexities. A derivative of the latter interest and of the dialogue with the U.S. curriculum theory, the question of knowledge was losing centrality to the notion of culture. That passing occurred differently inside the group, leading to the formation of other groups with different preoccupations.

### Mexico

Despite the negligible institutionalization of the educational field in Mexico, institutions such as the Mexican Council of Educative Investigation have made efforts since the early 1990s to foster research in that field in Mexico. Those efforts can be found in publications targeting educational production and in productions disclosed in the national congress organized by the association every 2 years.

The curriculum is one of the topics accorded special treatment by that association. Researchers of that field have specific space in the national event for publishing and presenting their productions and maintain an Ibero-American network of curriculum investigators that congregates principally Mexican researchers.

On that institutional basis, the curriculum field in Mexico has been providing visibility, on one side, to a vigorous questioning of the instrumental viewpoints predominating in Mexican curricular production, producing a theory that tries to articulate curricular questions in relation to issues of instruction and evaluation. The theoretical oppositions were added, particularly in the 1980s, to the political oppositions to the U.S. scientific viewpoints disclosed in the region, because the latter contributed to denying a socialist-based Latin American thinking.

The most critical production base does not prevent, however, the still accentuated development of studies that blend instrumental and critical viewpoints. In the years 1990 and 2000, viewpoints are still significantly present, centered on ways of planning and developing curricular designs, correlated

to the constitution of later native models for professional training and to the application of models and evaluation methods. Theoretical conceptualization works, even though existing and capable of influencing other countries of the continent, are influential, but not predominant in the country.

Consequently, the focus on the curricular proposition stands out based on the idea of an investigation that connects curriculum and teaching and seeks educational innovation. At times, institutional and governmental demands are strong stimulators of such works. One example is the diffusion of proposals associated to the curriculum by competencies. Although the restructurings of the working world displace qualification to competence and the curricular reforms in Mexico incorporate those proposals, associating them with proposals for integrated curricular organization, the academic sphere begins to dedicate itself to the thematics in a bias not necessarily analytical or critical, but above all, propositional.

We are mentioning the theoretical influence of the constructivist psychological approach, mainly in works associated with curricular development, with distinct hues that include, besides Coll, authors such as Jean Piaget, David Ausubel, and Howard Gardner. The poststructuralist and postmodern discussions, unlike in Brazil and Argentina, are of little significance. Also, there is almost a dearth of references to curriculum authors from other countries of the region, as well as texts in languages other than English.

### Argentina

The curriculum field in Argentina is still more recent and less institutionalized than in Brazil and Mexico, particularly due to the excellence of teaching as an area of study of matters of educational theory and practice. Only in the 1960s did the word *curriculum* emerge in official educational policy documents substituting study plans. At that moment, some professionals began to identify themselves as professionals of a field then characterized by its own technical knowledge. As in the rest of Latin America, Tylerian rationality prevailed. In a different perspective, a group of other intellectuals defended a progressivist perspective. Especially important was the development of a critical vision of the educational processes, centered

on the teaching profession. Between 1976 and 1983, the Argentine dictatorship stimulated the technocratic comprehension of the curriculum, at the same time expanding the technical body of curriculum thought and reducing the academic discussion of the field. With the end of the dictatorship, U.S. and English neo-Marxist authors and the reconceptualization movement began to be part of the field's agenda. Institutionalization of the field also expanded with the creation of curriculum chairs in various universities.

As from the 1990s, the curriculum field in Argentina broadened especially due to the general reforms of the educational system that took place in the period and the generalization of the process of teacher professionalization. From the thematic point of view, the link between the intellectual field and the activities of the official agencies is a strong feature of the Argentine curriculum field at the present time. In recent decades, the authors that had been prominent in redefining the field took on the task of curriculum formulators. Thematics such as curricular innovation, planning, and design are among the principal preoccupations of the field. Production ends up concentrated on curricular tasks, broaching thematics such as disciplinary curriculum, transdisciplinarity, and teaching by competences. From the theoretical viewpoint, constructivist standpoints, especially based on Piaget, share space with theoretical perspectives marked by technical rationality of a Tylerian hue. It is interesting, therefore, to note that the link between the intellectual field and political intervention, if an insertion of academia in practice is permitted, has reduced the critical and postcritical potential of the theoretical production of the curriculum field.

Looking beyond that group of studies, other focal points present in the production of the Argentine curriculum are the relationship between micropolitics, institutional cultures, and curricular dynamics; the relationships between educational policy and teaching action; and the history of the curriculum. Both the critical theory and the poststructural perspectives, especially Foucauldian, are important references in those studies. As for poststructuralism, in the second half of the 1990s the first studies emerged, a tendency that has lessened in this latter decade. Since the 1990s, Spanish, Mexican, and Brazilian authors had been added to U.S. and English references. Studies on curricular

theory continue practically nonexistent, in a way mirroring the field's minor institutionalization.

## LATINO/A RESEARCH ISSUES

---

Latino/a research issues resulting from the quality of the methodological design is beyond the scope of this discussion. This entry focuses on research issues in curriculum when Latinos/as as a population are addressed. It begins with a brief demographic portrait of the Latino/a panethnic group in the United States followed by a discussion of two common problems often present in the scholarship addressing curricular studies focusing on the Latino/a population. These problems include generic identification or labeling of the participant population and limitations in perceptions from researchers with outsider status.

### Demographic Portrait

The *Latinization of America*, a term first used by the Mayor of San Antonio (Texas), Henry Cisneros, two decades ago, is no longer prophetic in nature. Descriptive demographic snapshots show that the Latino/a diaspora is spreading quickly and completely across the entire country. The resulting dramatic exponential growth pattern of Latino/a students calls for research promoting changes in educational policy, curriculum design, and classroom practice. Data profiling the historical and continual neglect of Latino/a children clearly shows that this group is underserved. Public school conditions place this group at the lowest achievement level of any ethnic group in the United States; and the resulting academic outcomes follow children into adulthood. Today, Latino/a students display the highest dropout rates and the lowest high school and college completion rates.

Many in the country were probably not shocked when Latinos/as were proclaimed the largest and the fastest growing ethnic minority group in the United States. In fact, in 2006, demographers from the Hispanic Pew Center concluded that numbers were probably underreported because undocumented immigrants, with estimates as high as 11.5 to 12 million, were not included in official counts. Although the current growth is stimulated by immigration, 40.1% of Latinos/as are foreign born; the future projected distribution will be expressed through increased birthrates. Undoubtedly this dramatic demographic shift tests political, health, and economic structures and brings challenges to educational institutions. Currently, Latino/a children (under age 18) are the fastest growing and the second largest student population, after White students. Latino/a children account for more than half (58%) of all immigrant youth in the United States. Demographers project that within 40 years, one in four individuals living in the United States will be Latino/a. Presently, the United States ranks as the fourth largest Latino/a population in the world, trailing behind Mexico, Spain, and Colombia. The Latino/a diaspora establishes Latinos/as as the minority-majority in 19 states; however, almost half (49%) call California and Texas home, and approximately 74% live in five states—California, Texas, New York, Florida, and Illinois. In the United States,

the Mexican heritage ethnic group is the largest (66%), while Cubans is the smallest (4%).

### Research Issues

Research issues when members of a specific ethnic or racial group are under examination will likely be characterized by concerns particular to the group. In the case of Latino/a research, there are multiple aspects that might be addressed. For example, in terms of what is studied, some may claim that there is disproportionate attention to bilingual educational issues. When social scientists are positioning this population, there is a dualist tendency to present these children as victims or to romanticize their status in the subsequent interpretation of the findings. Likewise, especially in the conceptual scholarship, advocates tend to sensationalize serious issues facing this student population. This entry focuses on two issues: generic identification and limitations in outsider perspectives.

#### *Generic Identification or Labeling*

In 2008, the Hispanic Pew Center stated that one in five students in public schools is of Latino/a heritage. However, children from this growing panethnic group come from distinct ethnic groups with differing countries of origin, exhibit a variety of language skills, live in neighborhoods with families from diverse socioeconomic levels, and are socialized with diverse cultural beliefs, values, and skills that are often dependent on their citizenship status and generational position. In spite of the obvious in-group diversity found in individuals and groups within the larger panethnic group, research studies label and classify Latinos/as as a monolithic group. When describing Latino/a participants in a study, attention is rarely given to (a) membership in a particular ethnic group, (b) generational position in the United States, (c) citizenship status, and (d) other critical diversity factors influencing the study's outcomes such as the individual's socioeconomic status and language skills. For example, while both may be male, age 10, and Latino/a, a fifth generation, middle-class, English-speaking, Mexican American child has different economical, cultural, and schooling experiences than his native Spanish-speaking peer with minimal English language skills, with low-socioeconomic

status, who is a Salvadorian national and has lived in the United States for less than 2 years. In addition, racial identity factors need to be addressed in participant descriptions. Individuals from some ethnic groups, such as Puerto Ricans, Panamanians, and Cubans, can be classified racially as Black. Children with biracial and/or biethnic backgrounds must also be identified as such.

### *Outsider Researcher Perspectives*

Federal funding targeting Latinos/as, especially for the preparation of teachers to meet the needs of English language learners, has increased significantly. This upsurge in funding along with the exponential student population growth has generated a rise in researchers who study this population. Some of these new scholars hold an outsider status. They may not share ethnic group membership and bilingual language skills; others may not have adequate knowledge of this group's cultural values, beliefs, and competencies. These outsider researcher limitations may lead the researcher to inadvertently err in judgment and thus, ineffectively collect relevant data, make inaccurate interpretations of the collected data, or draw erroneous conclusions. Because outsider status is multidimensional, researchers perceived as insiders may not necessarily meet insider criteria. For example, a researcher with outsider status may include any of the following: Cuban scholars studying Mexican Americans; native born, middle-class Mexican Americans examining low-socioeconomic Mexican immigrant children; or non-Spanish speaking scholars researching a Spanish speaking population with minimal English skills. Cultural sensitivity and extensive knowledge of culture gives the researcher skills to observe the cultural nuances linked to language and ethnic heritage experiences essential to capturing rich data from the participants and interpreting the findings.

## LEARNING THEORIES

---

A learning theory is a set of systematic, integrated concepts and research-based descriptions of how individuals acquire knowledge, skills, and competencies, thus helping us understand the inherently complex process of learning. The relationship between curriculum and learning theories is a very close one. Curriculum is essentially a roadmap for learning and as such focuses on competencies and skills that are important to learn. Learning theories are frameworks educators consider when designing a curriculum and applying it to teaching and learning. With a learning theory as a conceptual framework, curriculum and instruction can be structured around making learning most effective.

There are many different theories of how people learn; therefore, it is hard to categorize learning theories in exactly the same way. In general, there are three main categories or philosophical and psychological frameworks under which learning theories fall: behaviorism, cognitivism, and constructivism. Behaviorism views learning as a measurable change of behavior resulting from environmental factors. Cognitive theories emphasize internal mental organization of knowledge, stressing the acquisition of knowledge, mental structures, and the processing of information. Constructivism views learning as a process in which the learner actively constructs new ideas or concepts based on prior knowledge and/or experience. Some variations of constructivism identify learning as more than the formation of habits, the processing of information, and the construction of knowledge, but rather a unique human activity by which individuals realize their inner selves and

make sense of life. Furthermore, postmodern and critical educators warn us about the limitations of these three main learning theories.

### Behaviorism

Behaviorism as a theory of learning that focuses on objectively observable behaviors and defines learning as the acquisition of new behavior through conditioning that occurs through interaction with the environment. Behaviorism was built upon the works of Ivan P. Pavlov, B. F. Skinner, J. B. Watson, and others. According to behaviorism, conditioning through associated stimuli is the basic process of all behavior and learning. People develop new stimulus-response connections and learn new responses to various situations through the process of conditioning. There are two types of possible conditioning: (1) classical conditioning, where the behavior becomes a reflexive or involuntary response to stimulus, and (2) operant conditioning, where there is reinforcement of the behavior by a reward or a punishment. Classical conditioning starts with a reflex: an instinctive, unintentional behavior caused by an antecedent environmental experience. It is the type of learning made famous by Pavlov's experiments with dogs. Operant conditioning forms an association between a behavior and a consequence—that is, learning is the result of the application of consequences. Learners begin to connect certain responses with certain stimuli, and this connection causes the probability of the response to change.

According to behaviorism, behavior can be studied in a systematic and observable way without considering internal mental states or cognitive processes of the learner. Behaviorism assumes a learner is essentially passive, responding to environmental stimuli. Behaviorists argue that adults shape children's learning by providing positive reinforcement. Learners' contribution to the learning process, such as purpose and efforts, and their individual, social, and cultural needs, are ignored in the development of behavioral objectives and the arrangement of learning tasks.

The curriculum for behaviorists should be organized around straightforward learning objectives and clearly stated learning outcomes. Behaviorists argue that anything that cannot be measured does not exist or cannot be important or trustworthy enough to play a role in the curriculum. Behaviorist

curriculum reinforces the structured learning that has predetermined objectives for what is to be learned, as well as predetermined reinforcers when objectives are met. In this type of learning, the end goal is defined up front, and each step necessary to achieve the goal is given to the learner. In addition, step-by-step conditioning programs are used to achieve the desired behavior, and rewards are used to motivate the learner.

Many curriculum theorists criticize behaviorism as an overly mechanistic one-dimensional approach to learning, a criticism that fails to take into account the environment the learning takes place in or the past experiences of the learner. Particularly, postmodern critical pedagogues denounce behaviorist visions of curriculum development that are characterized by behavioral lesson plans, context-free objectives, instrumental and external evaluation, and dualistic curriculum frameworks that detach teacher and student, meaning and context, subjective individuals and objective knowledge, and learning and environment. For the critical theorists, behaviorist curriculum models that aim to transmit value-neutral information to students are no longer acceptable in the multiculturally diverse postmodern societies.

### Cognitivism

Cognitive theories view learning as an internal mental organization of knowledge, stressing the acquisition of knowledge, mental structures, and processing of information. The focus of cognitivism on learning therefore is how learners process inputs and outputs mentally in order to understand how people think, learn, transmit information, and solve problems. Cognitive theorists believe that learners are actively involved in the learning process and that their prior knowledge and experiences play an important role in learning. Because prior knowledge and past experiences are essential for the comprehension of new information, teachers need to help students build the prerequisite knowledge.

Within the school of cognitive theories are several branching theories that examine the cognitive process from various perspectives. Well-known cognitive theories include cognitive information processing theories, which study how the human brain operates and how memory works; schema theory, which explores the existence of knowledge

structures; cognitive developmental theories, which are concerned with the relationship between cognitive processes and age; and the triarchic theory of intelligence, which describes and measures mental ability based on three elements of intelligence.

The cognitive approaches to curriculum development pay special attention to the higher mental activities of the learners, such as thinking, decision making, problem solving, and reasoning rather than the simple mechanic reinforcement emphasized by behaviorism. The cognitive approaches to curriculum development support the idea that better and faster learning can be achieved through the construction of learning environments that reinforce different learning styles. They aim to provide cognitive learning activities that have potential to extend a person's intellectual capacity based on the concept of distributed cognition and to expand a person's zone of proximal development. In these approaches, it is important to present all the necessary lower-level information to the learner before proceeding to teach at higher levels of the knowledge hierarchy in a subject matter.

In comparison to behaviorist theories, cognitive theories attempt to explain complex learning from a different perspective: how information was received, processed, stored, and retrieved inside the cognitive structure of the learner. Cognitive theories criticize behaviorism for being too dependent on observable behavior to explain learning. However, cognitive representation of learning even though in more complex forms is still largely a linear mental process of knowledge acquisition. Both behaviorist and cognitivist theorists recognize knowledge as existing independently from the learner. In this light, learning practice is understood as a matter of technical rationality, a problem solving based on procedural knowledge of how to achieve ends. Critical theorists argue that focusing only on what works and not paying enough attention to development of a critical, social, and political attitude toward teaching and learning may produce regulatory and disciplinary powers that serve as technologies to reinforce resources to Eurocentric and universalistic learning and curriculum theory.

### Constructivism

Constructivism is often articulated in stark contrast to behaviorism. From the constructivist

perspective, learning is not a stimulus-response event. Constructivism identifies learning as an active process in which individuals construct new ideas or concepts based on their past knowledge and/or prior experiences. Constructivist theory recognizes learners as active creators of their own knowledge, and learners interpret and construct a reality based on their experiences and interactions with their environments. In other words, learners construct their own understanding and knowledge of the world through their interactions with the world around them, rather than existing in the world as independent objects of truth. According to constructivist principles, meaningful learning is based on the active participation of learners in problem solving and critical thinking—given real and authentic problems.

Constructivism itself has many variations, such as inquiry-based learning, transformational learning, experiential learning, discovery learning, problem-based learning, cooperative learning, and situated learning. Further, within constructivism itself, learning theorists perceive the constructivist perspective differently by emphasizing different concepts. Nevertheless, there is some agreement on identifying constructivist learning theory in two general forms: (a) cognitive constructivism that approaches learning and knowing from the perspective of the individual and focuses on individual cognitive processes and (b) social constructivism that emphasizes the social, cultural, collaborative, and contextual nature of knowledge construction.

The roots of cognitive constructivism can be found in the theories of Swiss developmental psychologist, Jean Piaget. According to Piaget, learning is understood as an active mental process of engaging the environment in order to make sense of phenomena in the world. Piaget identifies knowledge as something that is actively constructed by learners based on their existing cognitive structures. Therefore, all individuals interpret experiences in the light of their existing knowledge, their stage of cognitive development, and their personal history. For Piaget, learning should emphasize the process and not the product. Learning is a process of constructing meaningful representations of one's experiential world.

Social constructivism, on the other hand, was mainly theorized by a Soviet psychologist, Lev Vygotsky, and an U.S. philosopher, John Dewey.

Vygotsky emphasized the role of language and culture in knowledge construction. According to Vygotsky, language and culture play essential roles both in human intellectual development and in human perception of reality. For Vygotsky, language and culture are the frameworks through which individuals experience, communicate, and understand reality. Consequently, human cognitive structures are, Vygotsky argued, fundamentally socially constructed. Vygotsky identified scaffolding, which is a process to perform tasks that would normally be somewhat beyond the learner's ability without assistance and guidance from the teacher, as an important concept for social constructivist learning.

Dewey also identified learning as a social activity. For him, individuals' learning is closely associated with their connection with other people. Dewey criticized traditional education with behaviorist curricular frameworks for isolating the learner from all social interaction and toward seeing education as a one-on-one relationship between the learner and the subject to be learned. In contrast, social constructivist theories recognize the social and contextual aspects of learning and use conversation, interaction with others, and the praxis as an integral aspect of learning. For Dewey, social constructivist theories provide students with opportunities to actively explore, inquire, reflect on, and experiment with problems. The theories also challenge learners to question, draw connections, reflect, communicate, negotiate, evaluate viewpoints, outline problems, acquire and use evidence, and generate new knowledge, understandings, relationships, and products and transfer them to similar situations.

Whether knowledge is viewed as socially constructed or whether it is considered to be an individual construction has implications for the ways in which curriculum is conceptualized. A constructivist approach to curriculum involves student-centered and problem-based learning strategies and opportunities in which learners are exposed to a range of cognitive processes involving comprehending, analyzing, creating, elaborating, reflecting, critiquing, and reorganizing the body of prerequisite basic knowledge to build up new complex and comprehensive knowledge structures. A constructivist approach to curriculum provides students with the opportunity to identify topics in

which they are interested, research those topics, present their findings, and make democratic changes in their communities. This approach is designed to be learner centered, for it encourages students to select their own research topics rather than being told what to study. The process of curriculum development depends on the questions that are asked, and the questions depend on the context. This view considers the social, political, and cultural factors that shape the structures that are taken as real and indisputable in curriculum development.

## LEGAL DECISIONS AND CURRICULUM PRACTICES

---

Since early attempts by state legislatures to formalize public school systems and standardize curriculum, the courts have played a critical role in shaping the requirements and limits of curriculum.

The greatest impact of case law on school curriculum is on the role of religion, but litigation over school finance, secular values, and student equity has also affected curriculum practice.

Religious influence on public school curriculum has been a topic of debate since Ye Olde Deluder Satan Law of 1647 established publically funded, religious-based curriculum in schools of Colonial Massachusetts. Throughout the 20th century the courts established a legal framework that balances the desire of some communities to infuse religion into its public school curriculum, with the requirements of the establishment clause of the First Amendment. Although a limited forum remains for the discussion of religious texts, observance of religious holidays, and learning religious-based music, the courts have clearly rejected school curriculum that advances or inhibits religion. There have been several attempts to challenge restrictions on prayer in schools. Similarly, court battles continue that attempt to address the conflicts between religious teachings and science curriculum.

School finance litigation has evolved since the early 1970s from an emphasis on student equity to adequacy. Outcome-based measures of adequacy have increasingly injected the courts influence into matters of school curriculum and assessment. Although the courts traditionally avoid acting in the role of a school board, in some cases they have been uncharacteristically prescriptive regarding school funding and outcome measures. The reason for this is that the courts must, to some extent, develop a working definition of adequacy in order to determine whether a state educational system is in compliance with an adequacy standard. The result has been a judicial discussion not only of what constitutes an adequate curriculum, but also of how different parts of the curriculum are to be funded.

Social values have long been the driving force behind curriculum development at the local level. The courts have often been put in the position of determining the constitutionality of structuring schools based on, and teaching children, certain social values that may be in conflict with individual rights. Attempts by the state to impose cultural assimilation through bans on non-English language curriculum and compel acts of nationalism through forced pledges have been litigated and struck down

by the courts. However, efforts by the state to compel both education and medical treatment that serves the greater social welfare have largely been supported by the courts. The greatest conflicts of social values have dealt with student equity as schools have served on the frontlines of social change movements promoting individual rights. The fair treatment of students and equal access to curriculum for people of different race, gender, and sexual orientation has been influenced greatly by court decisions.

## LESBIAN RESEARCH

---

Lesbian research is inquiry that focuses on the lives, experiences, and meanings of those who are socially identified as lesbians; this identity label is temporal, culturally determined, and socially constructed. Today, lesbian refers to women who are primarily sexually and romantically attracted to other women. Lesbian research is indebted to the advances and insights of feminism, a movement for social justice centered on women. Reflecting this historic connection, lesbian research has attempted to redress the imbalance of attention to dominant groups in traditional inquiry by calling attention to and countering the invisibility of lesbians through sustained investigation. This approach is aligned with a range of curriculum studies orientations including social reconstruction, feminist

critique and gender analysis, reconceptualization, critical perspectives, autobiography and biography, and more recently, queer theory.

### Lesbian Research and Social Movements

Lesbian research, with other identity-specific inquiry domains, represents the growth and successes of identity-based social movements for justice beginning in the 1950s and continuing into the 1980s, including Black power, the Chicano movement, women's and gay liberation, disability rights, and the American Indian movement. Participants in these movements fought to gain rights and access to social institutions, including higher education, and to establish interdisciplinary departments and programs of study focused on the often ignored and obscured histories and daily lives of these and other minoritized groups. For example, Black, Chicano, and ethnic studies programs preceded the first women's studies program in the United States, which was established in 1970. Women's studies provided an academic home for the social analyses catalyzed by and emerging from the women's liberation movement, in particular through radical feminist consciousness-raising groups initiated in the 1960s, where women rapped about their lives to share personal experiences and recognize common conditions and patterns in what formerly seemed like individual and isolated problems.

#### *Popular Education: Personal and Political*

The strategy of consciousness-raising reflects the common use of popular education methods in social justice movement organizing, as for example, at the Highlander Folk School in Tennessee, which was cofounded by Myles Horton and Don West and modeled after adult rural high schools in Denmark started in the 19th century, and played an important role in labor and civil rights organizing. Highlander's Citizenship Schools, which taught African Americans to read so that they could vote, were led by Esau Williams, Bernice Robinson, and Septima Clark, Highlander's Education Director, and started in 1954. Civil rights activists also built on popular education ideas when they developed a curriculum for Freedom Schools opened during the 1964

Mississippi Freedom Summer; it posed a series of questions for students to discuss in groups:

What does the majority culture have that we want?

What does the majority culture have that we do not want?

What do we have that we want to keep?

As popular education did at the time of the civil rights and early Black power movements, women's movement consciousness-raising used personal reflection and testimony and analyses of social norms to begin to develop new feminist theory and plans of action against the oppression of all women, perhaps best characterized by the feminist catchphrase, "The Personal is Political." In 1970, Robin Morgan included a description of consciousness-raising attributed to Kathie Sarachild in the germinal compilation, *Sisterhood is Powerful*. The volume, together with *Home Girls: A Black Feminist Anthology* and *This Bridge Called My Back: Writings by Radical Women of Color*, two 1980s edited volumes, can serve as a model of the evolving curriculum of women's liberation movement thought at the time; all include work by and about lesbians.

#### *Lesbians and the Curriculum*

Feminism made conceptual and practical space for attention to the lives and experiences of women, including lesbians; in particular, programs of women's studies in institutions of higher education, fostered through the labors of feminists, created institutionalized support for lesbian research. For this overview, lesbian research means inquiry into all aspects of the lives of those socially identified as lesbians (either by themselves or others), from meanings to material conditions; another sense could be research done by lesbians. As a complicating factor to both these connotations, identified by Suzanne De Castell and Mary Bryson in their essay, "From the Ridiculous to the Sublime: On Finding Oneself in Educational Research," there is a telling absence of lesbian students, teachers, administrators, and researchers in educational research accounts. Lesbians are generally part of the null or unstudied curriculum, while heteronormativity—the ways that heterosexuality is legitimized and

made to appear natural and normal through society's structures of power—is the hidden curriculum, or the ideological message of the rightness of heterosexuality embedded in the explicit curriculum. It is difficult and even dangerous to be known as a lesbian in education; the discrimination experienced by sexual minority teachers and students is well documented; this line of inquiry constitutes one important avenue of lesbian research. However, professional as well as social norms render it difficult and stigmatizing to be a lesbian researcher in education; although this condition has been noted by some researchers in published inquiry, including Bryson and de Castell, it may also reduce the number of lesbian-centric research projects undertaken and published.

### Feminism, Curriculum Studies, and Lesbian Research

Feminist frameworks from the 1970s and 1980s included a liberal strand that focused on analyzing and ameliorating discrimination against women and girls and two radical feminist tendencies—an essentialist analysis that argued for innate differences between women and men (girls and boys)—and a materialist position that emphasized the social construction of gender and with that, the possibility and even imperative of deconstructing the gender system. These frameworks have shaped forms of lesbian research legible within curriculum studies today, where they are sometimes overlapping.

Progressive era—approximately from the 1870s to the 1920s—intellectuals argued that the artificial environment and curricula of schools miseducated youth; they posed another possibility—that schools should help to develop a new social order through the promotion of active participation and learning by doing. The time saw a rapid shift from a rural agrarian economy to urbanization and a concurrent proliferation of women activists with broad social engagements who were also involved directly in public education reform efforts, including Jane Addams and Ellen Gates Starr, cofounders of Hull House in Chicago; Lucy Sprague Mitchell and Caroline Pratt in New York; and many others. Of note is that these prominent feminists were creating the new social order for women and girls through their doing by remaining unmarried; working at careers; living independently or collectively with

other women; claiming public political affiliations, such as to socialism and trade unionism; and participating in social reform activism and political research. These societal shifts laid the ground for the development of lesbian communities and rights-based movements for women and sexual minorities, among other groups.

Feminist critiques of education began to emerge throughout the late 1960s and 1970s and had two main focuses and corollary goals—the first was to analyze inequities for girls and women in education through close readings of texts and audits of activities for stereotypical and overtly discriminatory perspectives and practices, and the second was to develop theory explaining how gender is produced and maintained through social structures. Both of these directions had direct effects on education and curriculum studies. Specifically, the former orientation led to changes in textbooks and mainstream curricula, such as more inclusion of women as a focus in history, discussion of gender in the media, and policy shifts regarding gender-based curricular requirements (such as shop for boys, home economics for girls); the latter has had perhaps more effects on higher education and curriculum discourse than on schools. During these years and the 1980s, lesbians organized as a political force within feminism, and some of those within education began to write about their experiences; an example is *The Lesbian in Front of the Classroom: Writings by Lesbian Teachers*.

Feminism through this period often overlapped with critical (stemming from the Frankfurt School) or socialist, Marxist, and other politically left perspectives and activism, and some of the earliest gay and lesbian organizers were also members of the Communist party and Marxist groups. In general, critical or materialist theorists then and now have maintained a primary focus on class, with secondary interests in race and gender. Within criticalist or political curriculum studies, sexualities generally and lesbianism specifically were and arguably remain nearly invisible. In one instance of critique, in 1988 Elizabeth Ellsworth argued that feminist pedagogy and critical pedagogy are distinct and that critical pedagogy should become informed by feminism and poststructuralism, which could deepen its abilities to explain society's structures of domination, and specifically, how those operate through gender and sexuality normativities; greater

use of feminist frameworks could create openings for critical lesbian research in curriculum studies.

Separate from this strand of feminist curriculum discourse, also through the 1970s, feminist curriculum theory began to address the importance of autobiography and biography as ways to counter the dominant (patriarchal) discourses and establish and recover women's experiences, knowledges, and histories. Janet Miller and Madeline Grumet worked aspects of this terrain through the late 1970s and early 1980s, with Miller relating her feminist theorizing in curriculum and autobiography to the insights of philosopher Maxine Greene, who has written extensively about women in education and the importance of self-awareness to social change. Grumet and Miller both played germinal roles in the reconceptualization movement in curriculum, which called for the creative reworking and reorganizing of the field; Miller helped convene conferences and to establish the journal *JCT* (then, *The Journal of Curriculum Theorizing*; now, *JCT: An Interdisciplinary Journal of Curriculum Studies*); Grumet cowrote, with William Pinar, an early reconceptualist work, *Toward a Poor Curriculum*. Reconceptualism's inroads in curriculum studies, paired with the ongoing influences of feminist scholars such as Greene, Grumet, and Miller, helped to create an infrastructure—publishing, presenting, and intellectual community—to support an expansion of lesbian research in curriculum studies.

Through the 1980s, 1990s, and the first decade of the 2000s, lesbian research has been increasingly available in curriculum studies journals and conference venues and in books in the field. Many of these research projects link lesbian and gay and focus, as did some earlier feminist efforts, on reforming education; for example, the publications often address the experiences of sexual minority youth in schools. Other works report on and theorize about the lives and histories of sexual minority educators, such as Madiha Khayatt's *Lesbian Teachers: An Invisible Presence* and Jackie Blount's *Fit to Teach: Same-Sex Desire, Gender, and School Work in the 20th Century*. An example grounded in feminist and reconceptualist discourses is Miller's chapter, "Autobiography as a Queer Curriculum Practice," which paints a picture of the writer's autobiographical presentation at Bergamo, the conference sponsored by *JCT*,

during which she reveals her new relationship with a woman; the essay discusses her goal of "queering" or denaturalizing her many identities, including one as a lesbian, through autobiography. As in this work, many publications from the 1990s to the present reference queer theory. For example, *Negotiating the Self: Identity, Sexuality and Emotion in Learning to Teach* by Kate Evans uses the terms lesbian and queer almost interchangeably, and the book draws from a range of theoretical frameworks and research methodologies, including autobiography and critical discourse analysis, and closes with recommendations for teacher education.

Although lesbians are present in education and curriculum studies specifically, they are not as often noted in the field's synoptic and other foundational texts. For example, lesbian is not included in the subject indices of William Schubert's *Curriculum: Perspective, Paradigm, and Possibility* and Pinar, William Reynolds, Patrick Slattery, and Peter Taubman's *Understanding Curriculum*, though there are entries for gay, homosexuals, and queer analysis in the latter. Gay and lesbian is in the subject index of *Curriculum Books: The First Hundred Years, Second Edition*, by William Schubert, Ann Lynn Lopez Schubert, Thomas P. Thomas, and Wayne Carroll. But lesbian is not included in Pinar's more recent *What is Curriculum Theory?* though its subject index notes heteronormativity and queer theory. If only reviewing these texts, one might think the field leapt directly from the invisibility of all sexual identities, to male sexual minority identities with a brief stop at lesbian (after gay), and to queer theory and its critiques of sexual norms in curriculum. In other words the field seems to barely stop at lesbian as a category worth investigation by itself, rather than just one aspect of sexuality studies, to be paired with other aspects if explored at all. Although the category queer creates some new possibilities for challenging and remaking gender, sexuality, and other identities, it may also translate into less attention to *lesbian*. A review of available articles indicates that lesbian research in curriculum studies is available in education journals and through online databases, but there are notable and persistent gaps in focus. As one example, international lesbian research and lesbians of color are both underrepresented in curriculum studies, though gaining

visibility in the broader field of education; *Troubling Intersections of Race and Sexuality: Queer Students of Color and Anti-Oppressive Education*, edited by Kevin Kumashiro, for example, includes chapters by and about African American, Chicana, two spirit, and Asian lesbians, and recent work by Australian researchers Mary Lou Rasmussen and Jane Kenway bridges both the continents and the cyber divide in their discussions of queerness. Scholars in curriculum studies continue to be challenged by the perennial questions that have invigorated the field for decades, including asking whose knowledges, experiences, and histories count.

## LIBERAL EDUCATION CURRICULUM

---

Liberal education curriculum is a course of study of exemplary intellectual and artistic works across the disciplines, including history, philosophy, literature, fine arts, mathematics, and science. Proponents of liberal education believe that when individuals attain deep understanding of age-old existential quandaries, they will become well rounded, moral, and wise; moreover, they will become liberated from living merely by habit and unexamined belief. Although intellectual achievement is an important goal of liberal education curriculum, so too is the development of character. This curriculum's adherents express faith in liberal education to humanize students by cultivating spirituality, moral sensitivity, self-understanding, intellect, rationality, discipline, the powers of good judgment, and knowledge about of how to live deliberately and humanely as a good citizen within society.

The idea of liberal education stems from ancient Greece and the Socratic tradition of intellectual and moral training to prepare individuals to participate as citizens within a democracy. Greek and Roman Stoic philosophers also argued for liberal education as preparation to become world citizens by gaining the ability to understand different cultures and recognize the humanity of other people. Traditionally, however, this curriculum was meant to educate leaders, in particular, the few who would receive a university education; therefore, most discussion of liberal education curriculum has centered on higher education and the need for liberal or liberal arts education as the foundation of university curriculum.

Over time, liberal education curriculum was recommended for secondary students who could obtain a college education; notably, in the United States in the late 19th century, the Committee of

Ten proposed an academic liberal curriculum because most high school graduates would have prepared for the university. It was not until the later half of the 20th century, in the context of increasing college enrollment and in response to anti-intellectualism of U.S. society as well as lack of academic rigor in secondary education, that devotees such as Robert Maynard Hutchings and Mortimer Adler argued that liberal education would benefit all students and not just a university-bound elite. Contemporary supporters of this curriculum have made the case that it is the right of all students to learn from the powerful ideas of a humanities curriculum, not only because of the transformative power of such study, but because liberal education provides cultural capital for full participation in society.

In their belief that liberal education can be transformative, advocates of this curriculum feel strongly that teachers have crucial responsibilities. Because of the rigor of curricular content, wise and masterful educators who lead, coach, and guide students toward the cultivation of intellect and character are envisioned. When students cannot immediately see the value of study, educators with pedagogical expertise can help them to make connections between their personal lives and for example, great works of literature—to examine moral issues confronted by literary characters and to contemplate ethical dilemmas in their own lives. Teachers continue the tradition of Socratic questioning to stimulate genuine doubt and reflection to foster development of critical thinking and reasoned judgment. To teach this curriculum, educators are called on to have deep disciplinary and interdisciplinary knowledge so that they may stimulate rich multidimensional learning. The ideal image of a liberal education classroom is a community of scholars, often pictured as a Socratic seminar in which students engage in thoughtful discussion artfully led by their teacher.

The curricular content of liberal education begins with a fundamental multidisciplinary knowledge base. For this reason, universities and schools have provided a platform through general education requirements to allow students to achieve a full and balanced course of study. Furthermore, a number of universities and secondary schools have offered a thematic core curriculum not only to provide grounding in the disciplines, but also to promote

intellectual and ethical inquiry. Specific works of the core curriculum are chosen because of their enduring worth based on their potential to engage learners intellectually, artistically, and morally.

The liberal education curriculum has been at the heart of several academic controversies. Critics have attacked its emphasis on historically great works as elitist and out-of-touch with a modern, interactive, global, and technological society. Its sanctioning of particular cultural values has led to concerns of it being a culturally imperialist approach to education. Recent scholarship on liberal education has addressed these critiques by offering resolutions so that this curriculum might continue to be relevant in the 21st century.

Contemporary scholars, therefore, have tried to expand the notion of liberal education in several ways. By encouraging understanding of democratic citizenship through social engagement and community learning, liberal education advocates believe that students can cultivate habits of inquiry, judgment, and action. Hence, they call for liberal education to be evolving, dynamic, and pragmatic rather than being static and concerned primarily with eternal truths. In addition, contemporary proponents insist that moral dilemmas posed within exemplary works can and should focus on critical postmodern themes of injustice, oppression, and racism; for instance, they view both critical or feminist scholarship as compatible with and an enhancement of liberal education curriculum. Moreover, while still critical of the White, male Western European canon and its underlying assumption of cultural supremacy, other scholars imagine how liberal education curriculum can create world citizens who have deep cultural and cross-cultural knowledge. Such positions honor the liberal education tradition yet broaden it so that students can learn about what it means to be human and wise from the traditions, values, and contributions of more than one perspective and culture.

## LIBERATION THEOLOGY

---

Liberation theology originated in Latin America in the 1960s as a critical, theological response to overwhelming conditions of poverty and oppression. Grounded in a century of focused development in Roman Catholic social teaching, beginning with the 1891 papal encyclical *Rerum Novarum* and culminating with the Second Vatican Council's 1965 *Pastoral Constitution on the Church in the Modern World*, numerous Latin American theologians began to articulate a distinct theological method identified as critical reflection on praxis in light of the Word (as expressed in scripture and ecclesial tradition). This method highlights the primacy of experience as a source for theological reflection, noting that experience precedes theological formulation, and advances a preferential option for the lived experience of the poor. Liberation theology has both been informed by and informed the critical pedagogical work of the Brazilian educator Paulo Freire, with liberation theologians evidencing particular reliance on Freire's understanding of conscientization as critical participation in emancipatory, transformative action within history. Curriculum studies scholars have explored parallels between liberation theology and the method of *currere* as developed by William Pinar and identified a language of possibility and transformation within liberation theology that can inform a practice of critical pedagogy.

Early Latin American liberation theologians include Peruvian Dominican Gustavo Gutierrez, Uruguayan Jesuit Juan Luis Segundo, Brazilian Franciscan Leonardo Boff, and El Salvadoran Jesuit

Jon Sobrino. Articulating a theology of the periphery, in contrast to a European and North American theology of the center, liberation theologians emphasize solidarity with God and others that acts against oppression within the current historical moment. Concerned primarily with the circumstances of those living in poverty, expressions of this theology have also considered political, cultural, and gendered oppression. It identifies temporal liberation within history as a sign of the eschatological liberation to come beyond history. Critiques within the Roman Catholic hierarchy that led to institutional restrictions on the practice and role of liberation theology center on two related concerns: (1) the view that its emphasis on the pursuit of liberation within history negated anticipation of the fullness of liberation in the Kingdom of Heaven and (2) the perception that its use of Marxist analysis, particularly in relation to class struggle, prioritized political revolution. Liberation theologies have been articulated by scholars working from a range of distinct perspectives, including Rubem Alves' analysis from within Protestant Christianity, Sharon Welch's proposal of a feminist theology of liberation, Cornell West's discussion of Black liberation theology, and Marc Ellis' development of a Jewish theology of liberation.

In *Pedagogy of the Oppressed* and subsequent works, Freire theorizes education as a liberatory project advanced through conscientization, described as a process of critical reflection through which people gain insight into the sociopolitical structures of their world as well as the capacity to act to transform oppressive dimensions of those structures. Developed from within his experience advancing literacy among poor and indigenous persons in Brazil, a goal critically oriented toward obtaining the political right to vote in presidential elections, Freire's view of conscientization informed both liberation theology and critical pedagogy. Specifically, it affords each a language of possibility and hope oriented toward action. Drawing on Boff, Henry Giroux, and Peter McLaren, Thomas Oldenski provides historically important documentation of both Freire's influence on the thinking and experience of liberation theologians in Latin America and that theology's influence on Freire's own thinking. An example of Freire's influence is seen in the Brazilian Bishops' 1963 adoption of his method of literacy through the movement

of education from the bases and the subsequent role of Christian base communities as an experiential source for liberatory theological reflection.

Several scholarly papers presented at the 1992 Bergamo Conference on Curriculum Theory and Classroom Practice began to theorize connections between liberation theology and reconceptualized curriculum theory. Joe Kincheloe proposed that liberation theology offers an emancipatory system of meaning capable of informing critical pedagogy. Patrick Slattery considered parallels between liberation theology's view of time, history, and hope and Pinar's method of *currere*. Specifically, Slattery observed that both Gutierrez and Pinar reference Freire's view that the human vocation is humanization and that pedagogy is mutual and dialogical. Slattery posited that both liberation theology and *currere* emphasize a living autobiographical relationship with the future and the past as necessary for personal development and social reform, noting that liberation theology provides insight for theorizing emancipatory curriculum and pedagogy in a postmodern context. Giroux has noted liberation theology's role in providing a language of critique and possibility that interrupts dominant discourses and advances emancipatory interests. McLaren has discussed similarities between Freire's notion of the prophetic church and the work of liberation theologians, specifically manifest in the effort to orient theological reflection toward moving critical reasoning into practical action. Additional educational scholars influencing the field of curriculum studies through their exploration of liberation theology include Sue Books, Barry Kanpol, James Kirylo, Thomas Oldenski, and Edward St. John.

## LIFE ADJUSTMENT CURRICULUM

---

Life adjustment curriculum emphasized the role of the secondary school in preparing students not for further formal schooling, but for successful engagement in the life activities of adult society. A rejection of the theory of mental discipline and a critique of academic formalism informed the rationale for life adjustment curriculum. The proposals of the Commission on the Reorganization of Secondary Education influenced the idea and practice of life adjustment curriculum. In some ways, life adjustment curriculum represented the culmination of several decades of progressive education theory and practice. Life adjustment education, however, was not a monolithic curriculum reform and is best understood in one respect as one man's career-long idea and in another respect as a diffuse, ill-defined, largely symbolic, and short-lived reform initiative.

In the late 1930s, Charles Prosser, who is credited as the inventor of idea and practice of life adjustment education, articulated a conception of education for life that represented a culmination of his lifework in vocational education. Prosser criticized traditional academic curriculum as too focused on preparing students for further education rather than for adult life and as essentially selective rather than educative in character and intent. Prosser maintained that what he variously termed life adjustment education, life education, or just education for living was the best preparation for life and for college life. Although he held that every secondary school subject should be useful to living, he proposed that half of the high school curriculum be devoted to life education and half be devoted to academic studies.

Prosser proposed that curriculum content should be selected according to four criteria that he

derived from E. L. Thorndike's psychology: Subject matter should be selected that offered a wide range of utility, should directly meet life demands, should be widely usable in life, and should meet both present and future needs of students. Applied to conventional subjects, for example, life education would emphasize the use of English in business correspondence, everyday applications of arithmetic, analysis of current events, acquisition of basic business knowledge, and the role of science in everyday life. Life education would feature classroom activities such as using the local community as a laboratory for experience, use of wide range of print sources of information beyond conventional textbooks, active participation of students in learning experiences, the teaching of study skills, emphasis on application versus regurgitation of information, and emphasis on purposeful problem solving and decision making. Prosser envisioned secondary education as an apprenticeship for life.

As a result of a resolution Prosser proposed in 1945 at a conference of vocational educators, the United States Office of Education launched an initiative to promote life adjustment education for the alleged 60% of students who were ill-served by either the vocational or academic components of the high school curriculum. Two commissions served as clearinghouses and catalysts to stimulate interest in life adjustment education through state departments of education. Because of differences of opinion among commission members about which students should be served, about the definition of life adjustment education, and even about what the name of their initiative should be (almost half of commissioners preferred the designation general education), it is difficult to define exactly what life adjustment curriculum was. It is even problematic to associate two school programs, the Illinois Secondary School Curriculum Program and the course Basic Living at Battle Creek (Michigan) High School with life adjustment curriculum because they preexisted the work of the two commissions and were affiliated with them mainly by name.

Suffice it to say, then, that life adjustment education sought to move beyond the traditional academic curriculum to address the actual needs of youth and is best understood as an effort to make the high school curriculum address the broader life needs, rather than the narrow

academic needs, of youth. Life adjustment education attracted hostile criticism from academic traditionalists, who had more success in defining life adjustment education than its advocates had. As a result, most historical treatments of life adjustment education reflect the views of its critics more than the views of its advocates.

## *LIFE IN CLASSROOMS*

---

With its reflective examination of the social conditions of classroom life, Philip W. Jackson's *Life in Classrooms* became a touchstone in the dramatic expansion of the concept of curriculum in the second half of the 20th century. Jackson's combination of an ethnographic study of classroom life and quantitative analyses of student and teacher experience revealed that much more was taught in school than the explicit subject matter and that the most lasting lessons might not be intended at all.

The book is divided into 5 chapters. The first chapter, "The Daily Grind," describes familiar classroom conditions, showing how the crowds, praise, and power that typify classroom life dominate children's experience and shape their developing role as students. Because schoolchildren typically live in a world with one adult and a score or more other children, they inevitably encounter delay, denial, interruption, and distraction. How children respond to these deterrents determines

whether or not they receive praise and approval from the teacher. To be seen as successful, children learn to accept authority and to adapt to institutional conformity. This hidden curriculum is seen by Jackson as both supporting and competing with the official curriculum.

The second and third chapters draw on numerous quantitative studies to argue that despite the compulsory routine of classroom life most children do not seem to have strong feelings about school and that inattention or disengagement may say more about the experience of going to school than about the contents of the curriculum. Remaining uninvolved can be a way for students to resist the messages of the hidden curriculum.

In the fourth chapter, interviews with 50 teachers reveal a tender-minded, idealized view of children that Jackson argues fits the teachers' dual role as both agents of the institution and protectors of the children who attend it. In the final chapter, Jackson questions whether learning theory or human engineering, however scientifically based, can successfully guide teaching and urges that a better goal than seeking to engineer perfect teaching is seeking to understand teaching.

Rather than a single-minded argument for reform, *Life in Classrooms* presents a complex portrait of schooling in which different readers have found different messages. The introduction of the hidden curriculum has provided reconceptualists, critical theorists, feminists, multiculturalists, and other curriculum scholars critical of schooling with a mechanism to explain how dominant groups use schools to maintain their legitimacy. The methodology of the book, especially its first chapter, encouraged the development of ethnographic curriculum research that focuses more on what students learn than on what teachers plan. The call to seek an understanding of teaching rather than to prescribe how teaching should be done provided a basis for the move to see curriculum work as fundamentally a matter of understanding curriculum, rather than of developing curriculum. Finally, the mere announcement of a hidden curriculum led to other ways of distinguishing aspects or dimensions of curriculum—official, intended, planned, taught, enacted, shadow, experienced, embodied, and null.

Although the hidden curriculum was almost immediately seen as the name for systematically

generated, but undesirable learning outcomes in children, *Life in Classrooms* does not draw such a clear-cut conclusion. Although bringing attention to the demand (on both teachers and students) for institutional conformity, the book reveals the complicated interplay between students' psychological withdrawal and teachers' efforts to engage. By withdrawing (Jackson argues), students resist the demand for conformity; and by seeking to make classroom life less regimented and more pleasurable, teachers diminish the significance of the demand for conformity.

Moreover, *Life in Classrooms* does not insist that the hidden curriculum necessarily induces undesirable effects. Jackson shows that students living in classrooms will, in one way or another, be socialized by the experience of everyday events. Jackson's insight into the enduring significance of the ordinary may be the most lasting contribution of *Life in Classrooms* to curriculum studies. The book teaches readers that both careful observation and thoughtful reflection are required to understand curriculum because the ends of teaching are neither obvious nor certain and because the means of teaching are constituted from the fluid, subtle, pervasive, and often contradictory circumstances of everyday life.

## LOOPING

---

Looping represents a curricular-instructional practice where a group of students remain under the guidance of a teacher for more than the standard

period of time (typically more than a single academic year) while they are promoted to a new grade level. After typically a 2- or 3-year period, students move on to a new teacher(s) and the original (looping) teacher returns to a lower grade level to work with a new group of students. Resting upon the premise that better curricular and instructional practices may be crafted by the teacher who has become familiar with the needs and interests of the students, looping is often used as a way to establish a small school feeling and stability to the educational process. The practice is said to lessen anxiety of students as they begin each new year and to build stronger relations among teachers and parents. Looping was implicit in the structure of education during the late 19th- and early 20th-century one-room school house where only one teacher was available to all students. Historically, the term teacher rotation has also been used to describe this practice.

Although looping's pedigree is not necessarily traced back to the progressive education tradition, such experimentation occurred at the elementary, middle, and secondary school level (especially in core curriculum courses). At times, efforts were made to keep students and a teacher together for more than 1 year, a practice which is common in Waldorf Schools where teachers and students stay together typically from the first through eighth grade. Progressive educators felt that the informed teacher could best craft the curriculum for adolescent youth and to serve as a better way to attend to academic, social, and emotional needs. The Ohio State University School, one of the six most experimental schools of the Eight Year Study (1930–1942), practiced looping at different times throughout Grades 1 through 12; in addition, the impact of looping was incorporated into the education program through the planned participation of the school librarian and arts specialists. An interesting question from some worried parents arose from teacher–student dynamics: What if a teacher and student did not get along? The school administration maintained that an important aspect of building community and establishing democracy as a way of life included resolving conflicts. Teachers believed that an aspect of a realistic learning community involved attending to and working through conflicts and strained personal relations. For this reason, what has later been viewed as a criticism of

looping was viewed as a way to make the educational experience richer and more realistic.

Presently, looping is seen, along with block scheduling, as an effective means of assisting low-achieving student populations. Many positive attributes are assigned to looping, including increased parental involvement and stronger teacher–parent relationships, more extensive instructional time and better curricular design in relation to scope and sequence, increased student attendance and retention, better teacher–pupil planning, and more positive classroom environment. From an educational administrative perspective, it is often noted that looping is an inexpensive educational reform.

The concept of looping has been introduced specifically into the field of curriculum studies by Nel Noddings as she describes the importance of continuity in education. Noddings reintroduces a basic assumption, common among 1930s progressive schools, that the classroom community, similar to a family, is a multipurpose setting. She maintains that a moral educational purpose is to care for children as a way to teach them to care for others and that the relationship of caring is developed over time and calls for educators to implement aspects of continuity into the curricular structure. One specific form is continuity of people, for which Noddings maintains that 3-year looping programs should be commonplace.

With the current trend toward elementary school specialization of subjects among teachers, looping at times is dismissed as academic concerns overshadow the emotional needs-based interests of students. Other disadvantages of looping typically discussed include the possibility of tension between teacher and student or among students and the potential for emotional strain caused by the separation between teacher and student. Yet looping proponents, at both the elementary and middle school level, suggest that more instructional time is gained during the 2nd and 3rd years of looping due to teachers' familiarity with students' interests and needs. Further, the strength of classroom relationships and emotional attachments can serve to reduce truancy.

## LYOTARDIAN THOUGHT

---

In the late 1970s, Jean-François Lyotard (1924–1998) was commissioned by the government of Quebec, Canada, to analyze changes in Western knowledge since World War II. In his report, *The Postmodern Condition: A Report on Knowledge*, published in 1979, Lyotard describes the erasure of culture and aesthetics with the incoming technological age, (mis)shaping advanced, industrialized societies, computerizing them and their concept of knowledge. Reality becomes bytes of information, and performativity becomes the legitimation of that reality. In schools, test scores (high or low) not only attest to one's knowledge acquisition but also legitimate (or not) one's values and methods of operation. We are the scores we produce, and our curricula are designed not to help students question, explore, and think, but to produce efficiently.

Lyotard's report is a warning as to where our performance driven society is headed and calls on us to "wage a war on totality." His report interrogates the present state of knowledge and challenges the totalizing power of modern metanarratives, grand écrits, wherein all problems and possibilities fit together so well that no space is left for questioning, for interpretation, or for the uniqueness of singularity. While committed to challenging this totalizing power of the metanarrative, the sudden popularity of the word postmodern (and its implied categorical separation from the modern) caused Lyotard to rethink whether he had chosen the right word for the process he wished to advocate.

The prefix *post* signifies a time that comes after, subsequent to, or coming later than, suggesting a

separated past, present, future—too strong a distinction for Lyotard. He later preferred the prefix *re*, which carries different signification: To rewrite modernity is to bring forth issues, working through the problems (and possibilities) inherent, but hidden, in the continual present, the now, pregnant with issues yet-to-be. Lyotard's (re)writing of the problematiques of modern metanarratives addresses the totalizing and terrorizing effects of modern representation. His rewriting of modernity has profound and wide ranging implications for the field of curriculum studies, particularly his attention to modern reality, rewritten as event, and the limitations of modern representation rewritten as language games and differend.

Although Lyotard was a committed Marxist and phenomenologist early on, he later found the master narratives of Marx and Hegel troubling: All was solved by history's inevitable march toward progress, toward a better life. He found Marxism in its view of social problems to present a flat reality. For Lyotard, reality is event-ful—full of events—and singular events cannot be fit into a grand scheme. Something of the personal, filled with desires, passions, hopes, is always left over, a surplus, something for which rational interpretation can not account. This event-ful reality brings with it a personal ethics that requires one to think through each and every situation, to accept the responsibility of such thinking through, and to develop a politics that is not formulaic.

There is a need, Lyotard claims, to free up the rigidity of the grand écrits by searching for ways that personal passions and political structures interplay with one another. Structures are needed, but they need to be flexible. The implication for curricularists is that one should neither willingly impose the structure of curriculum on students, nor dismiss the value of structure. Rather, teachers should attend to the situation, aid students to find their own interpretations within a curriculum, their own connections to, differences from, and reflections on curricular structures.

According to Lyotard, modern reason (human reasoning reified) effectively functions to make individuals want to be or to do what the system needs for its own efficient functioning. To counter this totalizing aspect of modernist reason, Lyotard draws upon Ludwig Wittgenstein's concept language games (to rewrite reason). What attracts

Lyotard to this concept of language games is the sense of contract among the players (conversants). Rules (structures) are there, but not prescribed or imposed; they are spontaneous, flexible, and event driven. Further, although there are overlaps among the rules of different games, as the games (or moves) are discrete, so the rules are incommensurable. Each game is thus its own unique event. Each game is local.

Lyotard was committed to social justice and tackled the limitations of representation in modern, rational law that marginalizes by demanding that all accept its validity and articulate their issues within its parameters. Rational law is blind to cultural differences. This difference is more than mere difference; it is, Lyotard says, a differend: a difference that cannot be negotiated for lack of a rule of law that applies to both parties, the impossibility of representation when there is no common referent. In the postmodern condition, one cannot resolve a differend, one can only recognize such. One can at best feel when a differend occurs. Such feeling takes one outside the logic of reason. It encourages one to bring forth the unrepresentable, to present the unrepresentable, or to present that not-yet-visible. A curriculum based on the sensitivity of feeling, Lyotard believes, would be a curriculum not merely incredulous of the totalization—terrorizing—embedded in modernity's grand écrits, but would be a curriculum continually rewriting the problems

and possibilities inherent in modernity. In short, it would be a postmodern curriculum, where the local, the event-ful reigns; and in this reign, each player has his or her own rights and responsibilities. This condition is indeed a fragmented one, but ironically strength lies in this fragmentation. Various petite réceits interact with/in community and through this interaction the unrepresentable becomes perceptible.

The postmodern condition is then, as Lyotard says, a part of the modern. It is the modern rewritten. It is the modern continually critiquing and exploring its now self, moving beyond the condition of grand écrits, into a condition of the local (the petite réceits), where differences allow, encourage, the new to become perceptible.

## MACDONALD, JAMES

---

James Macdonald (1925–1983) was one of the most important U.S. curriculum theorists of the 20th century. He taught initially at the University of Wisconsin, Milwaukee, and subsequently at the University of North Carolina–Greensboro, until his death. Macdonald never published a book, but his work can be found in disparate places, including numerous monographs, booklets, and out-of-the-way journals (such as the *Journal of Vocational Education*). After his death, Macdonald's son Bradley J. Macdonald published *Theory as a Prayerful Act: The Collected Essays of James B. Macdonald*, a gathering of some of Macdonald's most seminal works. His work may also be found in William Pinar's *Curriculum Theorizing: The Reconceptualists* and *Contemporary Curriculum Discourses*.

Most notable among the many features of Macdonald's work was his willingness to bring in wide-ranging resources having nothing to do with education to develop our ability to see in new and fruitful ways. Illustrative of such breadth was Macdonald's use of the work of the preeminent 20th-century philosopher, inheritor, and extender of the critical theory tradition, Jürgen Habermas; the educational thinking of the eminent mathematician and philosopher Alfred North Whitehead; the anthropological insights of Edward T. Hall; and the psychological theorizing of David Bakan. Although we now take for granted bringing in new

sources to enrich our thinking, it was Macdonald (along with, notably, Dwayne Huebner and Ted Aoki) who introduced this way of working to curriculum studies.

As wide-ranging as Macdonald's sources were, the focus of his work was always consistent in exploring the blockages to and the hope for liberation as the goal of education. He was concerned with the project of finding oneself as a human being and working out the destiny of being human. The Bradley Macdonald collection illustrates that in Macdonald's early essays Macdonald was concerned with what it meant to be a human being and how school life might contribute to, unintentionally interfere with or actively inhibit, the development of the person. As his thinking developed, he became increasingly concerned with the individual and with her or his mediation of experience. He brought in Habermas to explore blockages to communication and to understanding the processes of curriculum deliberation and design through an examination of various value bases for education practice, a Freirian perspective to further critique curriculum development processes, focused on both what worldviews are being promoted and who is involved in the decision making, and he brought in Whitehead to offer an alternative to instrumental thinking through Whitehead's stage-developmental notion, moving from a romantic naïveté in relation to knowledge, a focus on the technical aspects of knowing, eventuating, hopefully, in a new synthesis Whitehead termed generalization, all as models for thinking about

curriculum. As his thinking developed, he moved further and further away from alignment with any one school of thought. Exemplary of this move is arguably his most important essay, "The Transcendental Developmental Ideology of Curriculum Development." In this essay, Macdonald leaves behind the technical-rational (Ralph Tyler) and the political radical (critical theory and critical pedagogy), proposing a new way of thinking about human development focused upon play, spirituality, and cybernetics, leading toward a transcending of ordinary human experience into new realms of human possibilities. In an essay published posthumously (cowritten with David Purpel), Macdonald and Purpel continue a critique of curriculum thinking, again rejecting the schools of thought of both Tyler and his many followers with technological solutions to schooling, and the critical left with a focus, according to MacDonald and Purpel, on questionable political and cultural ends. Their problem with the Tyler school is not with the method itself, but rather that it is used for the wrong ends. In this essay, they focus on establishing platforms, attending to the signs of transcendent reality (such as play, awe, and humor), being aware of evil, making the human aspiration for affirmation and hope central to curriculum thinking, and having liberation as the goal of education.

Macdonald, throughout his career, sought to move beyond the neat categories of curriculum thinking and into new realms of human possibilities not yet fully known or understood. His legacy is the courage with which he explored the world around him and the driving insistence upon an intellectual honesty that demanded a better world not in already existing terms, but in terms to be developed by the actions of the young. An anecdote, perhaps apocryphal but nevertheless illustrative, from his colleague Purpel, serves to highlight the special qualities of Macdonald. They were walking outside of the Curry School of Education at the University of North Carolina at Greensboro one day. A group of kindergartners saw Macdonald from afar and flooded to him. They instantly recognized that he was one of them, ever seeking and ever innocent. Although Macdonald's work was intellectually demanding and always personally challenging, children understood who he was and gravitated to him. Macdonald asks us to become

like those children: ever seeking, ever curious, ever insisting on answers not yet fully understood and yet beckoning forward.

## MAGNET SCHOOLS

---

Traditionally, children go to schools that are closest to their primary residence. Magnet schools are public schools that allow students a choice regardless of school zones requirements. Magnet schools usually have special curricula or characteristics that distinguish them from others and make them attractive choices for students who desire an emphasis in arts, math and science, work preparedness, and so on.

Magnet schools are public schools that have to adhere to all guidelines and regulations of public schools, unlike charter schools, which are public schools with a charter that releases them from some of the regulations. School choice represented in magnet, charter, and alternative schools has provided educators, parents, and students with alternative options for the traditional schools that are plagued with low academic performance, high dropout rates, school violence, and lack of preparation for college or for the workforce.

Magnet schools usually have a comprehensive vision, plus educational aims, goals, and objectives that are in accordance with such vision. Magnet schools also have clearly designed curricula,

themes, and teaching practices that promote the magnet school's vision. In addition, they have budgets, policies, professional development, and evaluation plans that comply with public schools regulations. Magnet schools have marketing and recruitment plans as well.

Magnet schools took precedence in the 1960s and 1970s as a tool for racial desegregation and academic equality for many schools. Providing special features in magnets was thought to encourage parents to enroll their children in such schools regardless of their zone boundaries, crossing racial lines and integrating schools. However, schools that promoted certain types of curriculum, such as Afrocentric curriculum, were found to increase segregation among races as Stephen Sugarman and Frank Kemerer argued in their book on school choice.

Magnet schools were found to lead neighboring schools to examine their own practices and to improve their schools in order to compete with magnet schools. As a result, magnet schools that started as a desegregation tool became part of the school improvement movement. Lately, magnet schools have become a tool to combat the increasing migration of students to private schools. Over the last 20 years, magnet schools have become a very attractive choice for many parents to the degree that most magnet schools are not able to accept more than 10% to 25% of the students who apply for them. Magnet schools appeal to parents due to the following criteria:

- specialized curriculum with common interests such as arts, math, science, or cultural studies;
- parents' and students' choices in curriculum emphasis;
- strong parental involvement in the curriculum and teaching methods compared to public schools;
- improved attendance as a direct result of the learner-centered approach of the curriculum;
- improved students' motivation, which is a product of student's choice and involvement in the curriculum design;
- increased self-esteem of students as a result of students' empowerment by giving students a voice and ownership of their own learning;
- improved academic achievement compared to traditional public schools indicated by the

majority of studies on students' achievement in magnet schools; and

- specialized preparation for the workforce since magnet schools have specific curriculum areas that better prepare students for employment after graduation.

Magnet schools usually promote progressive, innovative, and effective programs that are characterized by curricular cohesion and parental involvement. Magnet schools have three distinctive features: (1) distinguished, progressive curriculum or instructional features; (2) freedom of choice; and (3) promotion of diversity.

Magnet schools are usually found in urban settings since the main purpose behind most of them is social integration. Some magnets are self-contained schools, while others are schools within schools. They usually are small in comparison to their traditional counterparts. In addition, they tend to start with short-term federal grants or funds, which make their long-term planning uncertain. For magnet schools to be successful, the community must be involved and supportive of their mission.

Edwin Merritt and colleagues argued that not only can magnet schools address the academic needs of students, but also they are effective means of addressing the issues of educational equality and parity. They pointed out that a large number of magnet schools in Connecticut and Florida helped integrate racial groups within these areas and combat socioeconomic disadvantages among minority groups in public schools. In Nevada, magnet schools successfully brought diversity to ethnically homogeneous schools.

However, a study of magnet schools' enrollment in Cincinnati, Nashville, and St. Louis found that poor children remained concentrated in nonmagnet schools. The researchers found that the majority of students in magnet schools had higher income and more educated parents as indicated by Bruce Fuller, Richard Elmore, and Gary Orfield's research. Similar studies found that within racial minority groups, parents with high socioeconomic and educational backgrounds were more likely to enroll their children in magnet schools than parents with lower socioeconomic and educational backgrounds as offered by Sugarman and Kemerer.

Can magnet schools actually serve to address the inequality of U.S. inner city schools? The

research on the effectiveness of magnet schools, albeit mostly positive, indicates that magnet schools failed to achieve their original mission: school integration. Jonathan Kozol insisted that magnet schools contributed to the further isolation of poor children who were left behind in traditional schools after more successful students moved to magnet schools. On the other hand, many educators argued that magnet schools, if focused correctly, can contribute to the advancement of U.S. public schools and to the success of students of urban schools.

## MALEFIC GENEROSITY

---

Critical-political discourses in the field of curriculum studies concern themselves with issues of power, privilege, and oppression with the aim of understanding how education functions to maintain unjust and unequal relations in a society. Malefic generosity is a concept from Freirean critical pedagogy that concerns the relationship between the oppressor and the oppressed and suggests a contradiction between pedagogical intention and pedagogical effect. Understanding the concept of malefic generosity can help to clarify why teachers with purportedly the best of intentions fail to achieve successful academic results

with students from marginalized or oppressed groups.

Paulo Freire, in his landmark book *Pedagogy of the Oppressed*, contrasts two forms of education. Hegemonic education functions to integrate students into the logic of an unjust system, fails to make existing structures of domination explicit, and does not provide conceptual tools to question, challenge, and overcome inequality and injustice. Its pedagogical method has been termed by Freire as banking education—a form of teaching and learning in which the student is considered an empty vessel to be filled with knowledge deposits by the teacher. This form of education promotes passivity and conformity. In contrast, emancipatory education is characterized by the examination and analysis of forms of domination in concrete situations, consciousness raising about ways to challenge structures of oppression, and solidarity between teacher and student. The aims of emancipatory education are freedom, autonomy, and the acquisition of conceptual tools to transform reality toward greater participation, justice, and equality.

Freire characterizes this emancipatory pedagogy as one of authentic, humanist generosity. However, the investment of oppressors, who hold political and intellectual power and resources, in the maintenance of their own privilege and power, precludes their authentic participation in the education of those who are oppressed. This preclusion raises the question of who will participate in the implementation of a liberating pedagogy. Certain members of the oppressor class do join in solidarity with members of the oppressed class and can fulfill the function of facilitators of *conscientization*, a term coined by Freire that signifies the exposition of social and political contradictions and the resultant learning that can lead to overcoming oppressive conditions. This role and function, however, is fraught with unanticipated or unintended consequences. People who shift allegiance to the side of the exploited or the oppressed carry with them many markers of class and privilege (e.g., speech patterns, body language, tastes), markers which if unexamined can result in conscious or unconscious bias, prejudice, feelings of superiority, condescension, and a failure to trust in their students' abilities to think and to know. Hence, although they have taken the side of the powerless and may truly desire to transform the existing unjust social order,

they can end up reinforcing the status quo. Such generosity is considered to be as malefic as the generosity of the oppressors, who though they may dole out favors, rewards, wages, charity, and knowledge, have no interest in transforming the basic structures of exploitation and domination.

There are a number of methods designed to obviate malefic generosity, though no method can substitute for long-term, committed comradeship and communion with those whom one would help liberate. The educator who would engage in emancipatory education must have an abiding faith in the potential of themselves and their fellow humans to grow and develop in meaningful ways and to transform unjust conditions of existence. There must be a deep commitment to decenter dominant forms of discourse and theoretical suppositions and a willingness to learn from those who are culturally different from oneself. Educators need to develop a profound sense of trust in students, trust that can only be cultivated through authentic dialogue. He or she must be willing to equalize the role of teacher and student so that education becomes not something one does for or to someone, but with each other. Concrete strategies for authentic education include shared decision making about what is worth knowing, what will be studied, how learning will be expressed, and how the classroom or learning environment is structured. Perhaps most important is the mutual cultivation of critical thinking and a commitment to action on behalf of creating a more just world.

## MAN: A COURSE OF STUDY

---

Man: A Course of Study (MACOS) was an upper-elementary-level, interdisciplinary social science curriculum that predominantly featured the principles of evolution and anthropology. Originating during the post-*Sputnik* educational environment when federal funds and university academics were ubiquitously present in curriculum design projects, MACOS was developed by Education Service Incorporation, a private, nonprofit organization that had been created by scientist Jerrold Zacharias. In 1962, Zacharias assembled a group of scholars who felt curriculum should teach children to act as investigating social scientists rather than teach an aimless survey of facts. These scholars, along with classroom teachers, collaboratively engaged in one of the most significant, federally supported education projects in curriculum studies history.

In 1964, Jerome Bruner, cognitive psychologist, assumed stewardship of MACOS, the elementary branch of the international, nonprofit Education Development Center's social studies' project. Bruner wanted to develop a curriculum that would help students respect, learn about, and be able to transfer general principles about humanity and the social world. Most importantly, Bruner wanted pupils to develop confidence in their mind's ability to question and interact with information. MACOS's content and pedagogical approach both reflected this goal.

The ideological superstructure of MACOS's content was man's nature and how it related to and was distinct from other species. This distinction was specifically explored through cultural forces' shaping influence on humanity. To focus on such expansive generalities, three guiding questions were proposed: What is human about human beings? How did they get that way? How can they be made more so? To illuminate these questions, five cultural forces (language, tool making, social organization, prolonged childhood, and humans' urge to explain) would be explored as the course progressed through its two major components: animal and cultural.

MACOS examined several animal species with increasingly complex life cycles, communication systems, social behaviors, and child-rearing practices. This examination began with salmon and herring gulls, which laid the content foundations for an in-depth analysis of baboons. Learning about each species revealed to students how human's biological and social nature compared with other organisms, with a final transition to MACOS's cultural component. This unit's goal was to help students realize how culture reveals both distinct differences and similarities between humans. Through the use of unnarrated film of the Netsilik Eskimo's hunter-gatherer society, students conceptualized humans' universalities and culture's influence.

To teach this content, MACOS employed diverse media and activities, thereby allowing educators to provide many and varied learning opportunities. These opportunities were buttressed by Bruner's four pedagogical principles: contrast, encouragement of hypothetical thinking, participation, and stimulation of self-consciousness. Contrast, found in the comparisons of humans versus higher primates, humans versus prehistoric humans, contemporary technological societies versus so-called primitive societies, and adult versus children, was designed to classify the course's content. Students were encouraged to develop hypotheses about the presented content. Models of reality and embodiments of important generalities incorporated games, role playing, and other participatory activities.

Beginning in 1967, MACOS was employed in schools throughout America, and in the early 1970s, began encountering resistance. Some parents challenged what they perceived as an elementary class promoting unchristian, wanton values and behaviors. Other parents and educators disputed these charges and enthusiastically supported MACOS. Eventually, MACOS's curriculum engendered such controversy that it reached the House of Representatives and a national audience.

The atmosphere was now more politically charged, and MACOS's opposition challenged continuous spending for the program, asserting that such patronage was misguided, unfair to commercial educational enterprises, and a federal usurpation of rightful, localized educational control. Supporters of the course rebutted that federal

support had helped develop novel, productive pedagogical programs that advanced student learning. Ultimately, negative publicity extinguished MACOS's governmental funding and sales, thus ending the curriculum's implementation.

## MARGINALIZATION

---

Marginalization is a process of becoming or being made marginal to centers of power, social standing, or dominant discourses. People can become or be marginalized as a result of either individual circumstance, by being members of historically oppressed social groups, or by choosing associations with particular ideologies. Ideas—even entire disciplines—can become marginalized by virtue of their threat toward, or insignificance to, institutional, economic, or political centers of power. These centers of power can be local, national, or global in scope. Both human (individual and social circumstance) and ideological forms of marginality are of interest to curriculum studies. Curricula can be examined on the basis of the ways they represent and relate to, or fail to represent and relate to, issues of race, class, gender, ability, and sexual orientation. Multicultural curriculum theory, in particular, has focused on these social categories. Curricula can be designed to either challenge or reinforce power relations around such categories. One task of multicultural education has been, at least ostensibly, to challenge

the status quo and, therefore, reduce the effects of marginalization by the curriculum. For some versions of multicultural curriculum theory, the goal is not only to reduce or eliminate the effects of marginalization, but also to educate for activism against marginalization in the larger social sphere.

Curriculum that encourages social critique is often marginalized. When curricula are designed to open complex questions to ambiguous responses—responses that require sophisticated interpretive work—those curricula pose particular difficulties, for example, for common accountability measures. Such curricula may also present problems for particular communities that find ambiguity difficult to accept, understand, or work with. On the other hand, a curriculum that rejects such ambiguity, but endorses a particular set of ideas may likewise be marginalized if those ideas are outside the mainstream societal norms in any way. As such, a state of marginalization belongs to no particular political, moral, or ideological standpoint.

The concept of marginalization is too complex to be reduced to a good versus bad dualism. To be marginalized is oftentimes to be subjected to various kinds of punishment such as rejection, invisibility, suppression of basic rights, and even violence. But invisibility, in some situations, can be advantageous when it leads to, for example, a reduction in scrutiny by an overbearing state or other center of power. What is more, margins are markers of difference. These differences are numerous and carry a range of psychological and material effects that are not equal in intensity or force. In this sense, identities are constituted by one's range of marginalizations. It is within these differences—these areas of marginalization—that individuals or groups may find the most fertile ground for learning and understanding as one so placed has need to understand both the marginal position and the center of power. As such, a marginalized position can be characterized by deeper insight and intelligence than a centralized position in the same sense that bilingual capacity is richer than monolingual.

Various types of marginalization—individual differences, membership in historically oppressed groups, marginal ideologies—may coexist within one body, further complicating our understanding of the functioning of marginalization. Everyone is marginal in some aspects. The ways in which one attempts to define or identify oneself has much to

do with who or what one attempts to define or identify as other to one. Indeed, marginality in all its layers is constituted by encounters with otherness. The social margins result from encounters across differences between in terms of race, class, gender, nationality, sexual orientation, and ability. And encounters across differences between transform all who are involved. Individual margins may be constituted by encounters across differences within—differences generated by socially and culturally produced psyches. Social and individual margins within one body give rise to yet another level of potential marginalization—the surprise offered by a breakdown of stereotype. Rigid categories at any level do not hold up under close scrutiny.

Given these intricacies, curriculum studies of marginalization are best approached through multiple theoretical lenses or multiple disciplines. A psychoanalytic standpoint, for example, will yield different insights than will a political, sociological, or economic interpretation. It is this requirement that might recommend a cultural studies approach to understanding marginalization over many of the more traditional and instrumental approaches within curriculum studies. Cultural studies, particularly from the tradition of British cultural studies that originated in the 1950s, is by definition inter- or even antidisciplinary and has been applied routinely to marginality studies. Reconceptualized curriculum studies of the 1970s to the present contain approaches that are compatible with cultural studies, and there are many representative studies of marginalization within that tradition.

## MASTERY LEARNING

---

Mastery learning is a philosophy about learning and teaching that essentially asserts that under appropriate instructional conditions virtually all students can learn well. It places on teachers the responsibility of student learning proposing that they can teach so that all students master most of what they are taught. The goal is to enable students to acquire some basic intellectual competencies ensuring that they can undertake the subsequent learning demanded of them by their schools and eventually their vocations and avocations and which will potentially lead to satisfaction increasing the chances for the development of positive feelings toward learning. Mastery learning strategy is an important development in the field of curriculum studies, which, although criticized for its mechanistic nature, many of its tenets include lesson plans and emphasize instructional techniques, planning and competency assessment, and particular knowledge and skills that are thought of as important for students to live and work in the society. This strategy is influenced by social behaviorism with emphasis given on the formulation of specific instructional objectives attained through instruction sequenced into small steps. The career reward for teachers who use this approach is that their teaching consistently results in high levels of learning for most of their students rather than for just a few.

Mastery learning is typically a group-based, teacher-paced approach to instruction in which students learn, for the most part, in cooperation with their classmates. It is designed for use in typical classroom situations where instructional time and curriculum are relatively fixed and the teacher has charge of a big group of students, and thus, although excessive amount of instructional time cannot be spent in diagnostic-progress testing, student learning must be graded. Students progress through a systematically approached instructional sequence as a group and at a pace determined primarily by the teacher who is the instructional leader and learning facilitator directing a variety of group-based instructional methods together with accompanying feedback and corrective procedures. Particularly, courses or subjects are broken into small units of learning at the end of which students

are tested and receive feedback on particular errors and difficulties. Also, students are provided the needed time to learn and the alternative learning opportunities in order to master the predefined intellectual and behavioral competencies. What constitutes mastery is set based on some clear criterion, and successful learning relies primarily on teachers and students rather than on technological devices. Although it can be also implemented in an individual based, self-paced format, it differs from the vast majority of such individualized instructional programs where the teacher primarily gives individual assistance when needed rather than being a principal source of new information. Also, in the latter programs, students generally work at their own pace, independently of their classmates, using carefully designed, self-instructional materials and move onto new material only after they have mastered perfectly each unit.

Many elements of mastery learning were observed via empirical research as integral parts of successful teaching and learning. Some of these observations included the conviction that many students lack the needed sophistication and motivation to be effective self-managers of their own learning; mastery learning's consistently positive effects, although it did not yield the large effects on student learning proposed as possible by its advocates; and the quality of instruction, the strikingly improved student learning outcomes, and the effectiveness of schools evidenced worldwide.

The idea of mastery learning was found by Benjamin Bloom in 1974. Yet the basic tenets of mastery learning were described in the early years of the 20th century by Carleton Washburne and Henry Morrison who discussed in their writings the idea that all can learn and learn well. Current applications of mastery learning are generally based on Bloom's learning for mastery model developed in 1968, based on John Carroll's conceptual model of school learning, which provided the theoretical basis for the strategy of learning for mastery that viewed student aptitude for a given subject as an index of the amount of time the student would require to learn the subject to a given level. Bloom's approach to mastery, the basic features of which have been summarized by John McNeil in 1969, requires that learning objectives are well defined and appropriately sequenced that student learning is regularly

checked and immediate feedback is given, and it stresses that student learning is evaluated in terms of criterion-referenced rather than norm-referenced standards. In the subsequent decade through the mid-1980s Bloom's ideas were refined by James Block, Lorin Anderson, and Thomas Guskey providing a more systematic and practical model focusing on defining, planning, teaching, and grading for mastery. Block and Robert Burns have written extensively on mastery learning and have elaborated on four types of mastery learning research, focusing on whether mastery approaches to instruction work, what might follow, why, and how and their practical, theoretical, and ideological implications.

In the mid-1970s, proponents and opponents of mastery learning argued about the pros and cons of the strategy. Critics of mastery learning assert that mastery approaches to instruction are rigid, mechanistic, training strategies; that they can only give students the simple skills required to survive in a closed society; and that they do not appreciate the complexities of school learning. Adherents of mastery approaches to instruction maintain that they are flexible, humanistic, educational strategies; that they can provide students with the complex skills needed to prosper in an increasingly open society; and that they do take into account the realities of classroom life. Nevertheless, the elements of mastery learning as proposed by Bloom and refined by others constitute a general foundation for educators at all educational levels to plan lessons.

## MATHEMATICS EDUCATION CURRICULUM

---

Mathematics curricula are popular, perceived as the most stable and the most universal of the disciplines that are represented in formal educational institutions. In terms of stability, many topics in contemporary texts were not just represented in medieval schools (with some tracing back to ancient Greece); the manner of presentation is often surprisingly similar across recent centuries. As for perceptions of universality, mathematics is by far the most common focus of international comparison testing. Although examination makers often must make minor adjustments for grade levels from one nation to the next, topics and expected levels of mastery are strikingly consistent in the developed world.

Yet a very different picture of mathematics curriculum is presented when one focuses on particular eras and locations. Not only does the what (the contents) of curriculum shift with time and place (i.e., the who and where), so do the when, why, and how. For example, the topic of common fractions is one of the mainstays of curriculum in most of the English-speaking nations. It is typically introduced in middle school arithmetic and serves as a major emphasis for several years. In France, however, the topic is only encountered incidentally in high school algebra, as minor subtopic of rational expressions—and for good reason. Having developed and adopted the international (Metric) system centuries ago, the ability to manipulate fractions is a rather unimportant competence in France.

Even where topics of study are reasonably stable—as they have been in North America over the last century, for example—shifts in pedagogical emphasis have contributed to substantial transformations in the character of school mathematics. Recent examples include the post-*Sputnik* new math movement of the 1960s in which the emphasis shifted from mastery of procedures to understanding logical structures and formal propositions. The more recent movements toward problem

solving in the 1980s and manipulatives in the 1990s have had impacts of similar magnitude, although not always of comparable coherence. It remains a topic of heated debate, for example, whether mathematics should be taught for or through problem solving. Although it might sound like word play, the difference is not a subtle one in practical terms.

Briefly, then, in spite of appearances, the mathematics curriculum is as volatile and context dependent as any other subject area. This short introduction is thus organized around points of apparent agreement, coupled to prominent tensions, ongoing evolutions, and emergent issues.

### Aims of School Mathematics Curriculum

Perhaps the most contested topic in school mathematics has to do with the purposes of engaging with the subject matter at all. At present, the overwhelming emphasis within the field of mathematics education is on the development of conceptual understanding, often contrasted with the mastery of technical or procedural knowledge. Such technical competence was the explicit goal of mathematics instruction a century ago—so much so that massive efforts at reform over the past few decades have done little to disturb the popular belief that mathematics, in fact, consists precisely of those procedures to be mastered.

This emphasis on conceptual understanding is a recent one. It is, in large part, borne of technologies that have eased the burden of technical competence, both within and beyond mathematics classrooms. In terms of curriculum topics and pedagogical approaches, the emphasis on understanding has prompted increased attention to explanation and justification and diminished interest in memorization and practice.

The major issue that arises here is around the tendency to dichotomize conceptual and procedural knowledge. To truncate current discussions, in order to develop more sophisticated insights, earlier ones must be somewhat automatic. A knower would be severely handicapped if compelled to reconstruct an idea or technique every time it is invoked. It is thus not a matter of which to emphasize when specifying a curriculum, but how to ensure a balance that supports both conceptual and technical development.

As obvious as this point might seem, current efforts at mathematics curriculum development tend to be mired in the math wars—popularly characterized in terms of a pendulum that swings between the poles of technical mastery and conceptual understanding.

### Topics in School Mathematics Curriculum

Technically speaking, the noun *mathematics* should be treated as a plural—that is, we should speak in terms of what mathematics are, not what mathematics is. The domain comprises many branches of inquiry, the most familiar of which are arithmetic, algebra, geometry, and calculus.

A frequent observation within the mathematics education community is that the topics and sequencing in most school mathematics curricula seem to be organized with the intention of preparing students to proceed into calculus. In most North American jurisdictions, the first 7 or 8 years are focused on arithmetic, developing understandings of and facility with different number systems. Early grades deal with whole numbers, decimal and common fractions are typically introduced toward the end of elementary school, and signed numbers and irrational numbers are introduced in the middle years in preparation for algebra. Most often, each number system is studied by looking at equality, addition, subtraction, multiplication, division, and exponentiation in sequence.

Algebra, or the mathematics of generalized arithmetical operations, most often begins toward the end of middle school. In many locations, the shift to algebra not only corresponds with, but also is used to define the commencement of high school mathematics. As with arithmetic, topics and sequencing in algebra curriculum tend to be quite similar across contexts. Typically, it begins with simple equations and then moves through multistep equations, systems of equations, polynomials, radicals, rational expressions, and sequences and series.

The most varied strand of school mathematics is geometry. Aspects of this branch of mathematics are usually distributed across K–12 curricula, and topics addressed in the higher grades tend to vary dramatically from one country to the next. Often topics in geometry are gathered under the categories of measurement, shape, and spatial sense in

contemporary curricula. In the early grades, topics such as identification of simple shapes, linear measurement, and uses of formulae to calculate area are typical. More sophisticated applications and a few elaborations (e.g., volume) of these topics are usually encountered in the middle years, but few new topics are introduced. At the high school level, a range of geometry-related topics might be encountered, including trigonometry, conic sections, and proof.

Calculus is most often included as an advanced option in most school jurisdictions—although it now commonly appears as a topic of required study in academic-stream mathematics. Even though it is not usually a part of the required K–12 curriculum, many topics in the higher grades (again, varying dramatically from one context to the next) are clearly intended to ease the transition into calculus. These topics include functions, vector algebra, matrix algebra, conic sections, and linear algebra.

As noted above, mathematics comprises many other branches of inquiry. A few others that are commonly encountered in grade school curricula are probability, data management (i.e., an adaptation and application of statistics, seen by many to be out of place in a mathematics curriculum), combinatorics, and problem solving (typically treated as a transcurricular, rather than a discrete topic). Other branches of mathematics are beginning to be represented in many grade school curricula, partly in response to a desire to present mathematics as a vibrant and evolving domain of inquiry. For example, fractal geometry is now commonly encountered. Less often, nonlinear dynamics and complex modeling are included in some curricula. Notably, most of these new topics are heavily reliant on powerful computing technologies.

### **Structures of School Mathematics Curriculum**

One of the features that distinguishes school mathematics curriculum from most other subject areas is its tendency to be explicit about the assumed structure of knowledge and the manner in which that structure might be employed to organize formal curricula. Indeed, it appears that most other disciplinary areas have borrowed from mathematics in this regard.

More descriptively, most modern curricula are organized around the ideal of the formal geometric proof, drawn from the mathematics of ancient Greece and championed by rationalist philosophers since René Descartes. Briefly, the model here begins with the statement of foundations truths or assumptions and proceeds by knitting those premises together into more sophisticated truths. From this structure we derive the tendencies to organize curricula around basics, to focus on formal principles, to organize concepts into elementary and advanced categories, and to sequence topics and subtopics into linear trajectories.

On this count, it is interesting to note that there is a growing movement in mathematics curriculum to rethink the structure of mathematics knowledge (and hence, mathematics curriculum) in terms of networks rather than hierarchies. In this frame, concepts and understandings are understood not in terms of foundations and a logical structure, but as coherences that arise among experiences and associations. So conceived, for example, the concept of multiplication is not a basic operation that is readily defined, but a complex of metaphors (e.g., number-line stretching, scaling), processes (e.g., folding, grouping), images (e.g., grid making, area producing), and algorithms (e.g., repeated addition, multidigit multiplication). Correspondingly, curriculum is reconceived in terms of major hubs or neighborhoods of ideas that resemble other neighborhoods. One does not move sequentially or incrementally through these neighborhoods. Rather, it is more a matter of gradual, recursive, and simultaneous elaboration of existing nodes and hubs.

This notion is actually gaining much more traction in postsecondary contexts where, as might be expected, concerns with coverage and standardized performance assessment are much less pervasive. It will be interesting to observe how the shift in sensibility might affect K–12 curricula in upcoming years. It is, of course, only one of many other emergent issues that are having an impact on current school mathematics curricula.

### **Emergent Themes in School Mathematics Curriculum**

Perhaps the most persistent question in discussions of school mathematics curriculum is that of relevance, so clearly articulated in the question posed

by almost every student at some point in their mathematics study: Why are we learning this?

This question is of increasing significance at the moment. The common contents of contemporary mathematics curricula were, for the most part, selected at the dawn of the Industrial Revolution—a time of very different social, technological, intercultural, and ecology conditions.

Socially, for example, most of the mathematical content that has come to be represented in public schooling was selected associated with the needs of workers who occupied a class that was rather sharply separated from upper and noble classes. Curricular distinctions that are based on class are, of course, no longer viable. In fact, they are now commonly perceived as oppressive and offensive. A related concern with mathematics curriculum traditions is what many perceive as a strong masculinist bias, one that some argue continues to privilege males. In fact, many have called for mathematics to be displaced from its privileged position at the center of the modern curriculum—a call that is tempered by critical theorists who note that school mathematics is among the most valuable of cultural capitals. To displace it might further disadvantage that already disadvantaged.

In a different but no less significant vein, the technology that has dominated mathematics research and education for millennia—formal symbolic manipulation—is rapidly being overtaken by electronic technologies. New techniques and tools, with increasingly user-friendly interfaces, are transforming every aspect of mathematical engagement from early learning to advanced research. One major transition, for example, is the emergence of an empirical mode of research in which mathematicians (and students of mathematics) are able to experiment with various aspects of mathematical constructs, thus opening up entirely new and unanticipated domains of possibility. There are clearly some profound curriculum implications, although they remain to be seen. At the very least, it is no longer easy to justify the months and years spent on, for example, long division and fraction addition.

On the level of intercultural dynamics, mathematics has been implicated in massive cultural oppressions in large part through its contributions to western economic, industrial, and military powers, in addition to the subtler platonist and rationalist sensibilities that are often associated with

mathematical thought. Two prominent movements to address these issues within the field of mathematics education are critical mathematics, concerned mainly with the Eurocentric and modernist biases of the discipline (particularly as represented in schooling), and ethnomathematics, concerned with mathematical insights from eras, cultures, and traditions other than modern, Western, and European. Some of these insights are coming to be represented in different nations, particularly those with strong postcolonial narratives.

A very similar line of thought has extended into discussions of the role of mathematics and emergent ecological, environmental, and sustainability issues. As an enabler of science and industrial technologies, mathematics is seen by many to be fully complicit in a range of contemporary crises. It is not yet clear how school mathematics curricula might be affected by this concern. At the moment, the topic has entered schooling through data management and various application exercises in different strands. It has not, however, emerged as a significant or coherent curriculum topic.

## MATHEMATICS EDUCATION CURRICULUM, HISTORY OF

---

The history of mathematics education curriculum is, in many ways, a history of formal education in

the Western world. Embedded in the contemporary school mathematics curricula are a full spectra of philosophies, a variety of contested rationales, and a set of incommensurate beliefs about learning and teaching—all of which attest to its long history and its central position in formal education.

### The Emergence of Mathematics

The conflicted character of mathematics education curriculum is anchored to the variegated history of the discipline itself, starting with the very word *mathematics*. Derived from Latin, Greek, Gothic, and Germanic terms having to do with thinking, having one's mind aroused, and wakefulness, mathematics originally had to do with a more general notion of learning.

The strands of thought included under the umbrella of mathematics have changed considerably over the last few millennia. Originally conceived as a rather broad category, mathematics once included (among other domains) geometry, astronomy, and optics. Indeed, the mainstays of modern school and university mathematics curricula—algebra and calculus—are relative latecomers to the group.

To complicate matters, until relatively recently, certain aspects of the current category of mathematics were distributed in very different ways within formal educational institutions. For example, medieval universities tended to organize their curricula around Plato's trivium (grammar, logic, and rhetoric) and quadrivium (arithmetic, geometry, music, and astronomy), an organization which in itself was a significant refinement of more varied mixes in the education systems that were typical of ancient Egypt, Rome, and Greece. A major transformation in this structure was prompted by the mathematical research of René Descartes (1596–1650 CE) who is generally credited with defining modern mathematics. His two major contributions were, first, to emphasize the role of logic in mathematical argumentation and second, to introduce the  $x$ -,  $y$ -coordinate system as a means to pull together geometry, algebra, and analysis into a coherent domain (rather than three distinct strands of thought). These moves continue to be reflected in the structures and contents of modern curricula.

### Key Moments in the History of Mathematics Education Curriculum

Setting aside the gross differences between ancient and contemporary conceptions of mathematics, it is fair to state that elementary mathematics (in particular, topics in basic arithmetic and plane geometry) were part of the education systems of most ancient civilizations, including ancient Vedic, Egyptian, Greek, and Roman societies. (Of course, in most cases, formal education was restricted to males of sufficiently high status.)

The most potent of these ancient influences on modern mathematics curricula is ancient Greece. On this matter, perhaps the three most notable in a long lineage of Greek thinkers are Pythagoras, Plato, and Euclid. Pythagoras (575–490 BCE) freely mixed mysticism, philosophy, and mathematics (in modern terms) as he and his followers developed a significant opus of mathematical knowledge and institutionalized its teaching. Plato (428–328 BCE), much influenced by Pythagoras, was the first to divide the trivium and quadrivium, and this structure was carried into the classical education of medieval Europe. Euclid (323–283 BCE) is noted both for his substantial contributions to geometry and for formalizing the logical proof. Indeed, the Euclidean deductive proof still stands as the hallmark of mathematical argumentation.

However, the major influence in the shape of modern mathematics curricula, as noted above, was Descartes. Not only did he help to define the contents of modern mathematics, he stripped away mystical elements and argued for a link between the structure of mathematics and the processes of learning. That link, the logical sequential movement from simple to more complex elements, has since served as the most common model for the structure of school curricula.

This is not to say that school mathematics, as now understood, started with Descartes. The beginnings are perhaps more appropriately traced to the first mathematics textbooks to be composed in French and English by Robert Recorde, textbooks which began to be published in 1540. Those texts had a decidedly algorithmic and utilitarian flavor, focusing on commerce and trade. With these emphases, the academic status of mathematics declined, and in Renaissance

institutions, it tended to be treated as secondary to studies of philosophy.

The trend was reversed in the 1600s, as evidenced by the establishment of chairs in English, French, and German universities. Even so, it continued to be unusual for mathematics to be taught outside of universities. It was not until the 1700s and 1800s, with massive industrialization and rapid urbanization, that mathematics became part of public education. Its early foci were fully utilitarian, concerned with simple arithmetic, counting money, telling time, and so on—in brief, the sorts of skills needed by a minimally literate workforce in a new urban setting.

By the early 1900s, mathematics was part of the core curriculum of all developed countries, and by the mid-1900s, a relatively uniform curriculum had spread around the world. This curriculum focused on arithmetic in the elementary grades and algebra in the higher grades, with topics in geometry distributed across levels. However, even though modern mathematics curriculum often seems to be stable and uniform, it began to be dramatically affected by shifts in thinking about how people learn and the purposes of school mathematics in the late 1900s. Although specific topics have changed little over the past few decades, emergent emphases on problem solving, communication, and argumentation have contributed to a fundamental redefinition of mathematics curriculum. The major move might be characterized in terms of a shift away from the utilitarian aims of earlier generations toward emphases on creativity and exploration.

## MERITOCRACY

---

A meritocracy can be defined as a system in which the rewards (wealth and privilege) are distributed according to individual merit. In other words, good things will accrue to those who work hard and do well. A meritocratic society is generally distinguished from an aristocratic one in which wealth, position, and privilege were received as a function of one's ancestry and family background. In theory, a meritocratic society is more fair because any individual has the possibility of being successful and achieving at a high level. In actuality, meritocratic beliefs are often linked to decisions about differential access to rigorous curriculum and high level pedagogy that maintain social-economic stratification among students. For this reason, conceptions of meritocracy impact greatly the areas of curriculum design and development and indirectly, have influenced research in curriculum studies.

The term meritocracy was first used in 1958 by Michael Young, a British sociologist, when he wrote a science fiction novel called *The Rise of the Meritocracy*. This satirical book depicted a society where people in power legitimated their status using merit as the justificatory terminology; those who were poor or left out were seem deservingly disenfranchised.

Our belief in meritocracy, often linked to the American dream that states that anyone can be successful with enough drive and effort, ignores the ways in which stratified societies tend to reproduce themselves.

In her new book, *Meritocracy Inc.: How Wealth Became Merit, Class Became Race, and College Education Became a Gift From the Poor to the Rich*, Lani Guinier argues that many of the criteria associated with individual talent and efforts (which should be rewarded proportionately) are actually highly linked to one's social position or opportunities gained by virtue of family and position so that while the system called meritocracy is supposed to be more democratic and egalitarian than aristocracy, it in fact reproduces the same distribution of power and rewards.

A strong belief in the existence of a meritocratic system often leads to a system of blaming those

who are not successful, associating their failure with lack of intelligence, drive, commitment, or effort. In other words, if the system is fair, then those who are failing have only themselves to blame. This analysis keeps us from looking at societal and structural barriers to achievement and avoids interrogating how racism, classism, sexism, and other oppressive institutions and practices manifest in highly differential achievement by various groups and individuals. Those who believe in meritocracy are often highly critical of programs of affirmative action, arguing that since the system is fair, there is no reason to provide special opportunities to those often disenfranchised or excluded.

In their book, *The Meritocracy Myth*, Stephen McNamee and Robert K. Miller, Jr. challenge the myth that the system distributes resources—especially wealth and income—according to the merit of individuals. McNamee and Miller do not deny that there is such a thing as merit; rather, they question the idea that societal resources are distributed exclusively or primarily on the basis of individual merit. They cite the interaction of merit with nonmerit factors such as inheritance, social and cultural advantages, unequal educational opportunity, luck and the changing structure of job opportunities, the decline of self-employment, and discrimination in all of its forms.

They explain that there are a variety of social forces that tend to suppress, neutralize, or even negate the effects of merit in the race to get ahead, factors which they refer to, collectively, as social gravity. These forces tend to keep people in the places they already occupy, regardless of the extent of their individual merit. Because these forces of privilege are often invisible, it is easy to miss the ways in which achievement is linked to inherited and accrued advantages.

Children of wealthy, privileged parents are far more likely to end up in programs of gifted education, for example, and poor children are more likely to end up in special education and remedial education. These decisions provide evidence that even what appear to be neutral measures of intelligence and aptitude are closely correlated to family background and income; meritocracy is still very much enacted through curricular and programming differentiation.

McNamee and Miller say that making Americans more genuinely meritocratic would necessitate radical effort to end discrimination, redistribute wealth, make taxation fairer, and increase the allocation of governmental resources for education and health care services.

## METATHEORY

---

A metatheory represents a conceptual framework offering both normative and empirical foundations for theory. A metatheory of the curriculum studies has fallen on hard times from a postmodernist perspective. In modernist curriculum theory, the search has been to provide some sort of comprehensive structure of knowledge and its transference through a variety of competencies such as learning skills and methods of inquiry, the idea being that it is possible to synthesize existing educational theories under a grand scheme to achieve such an end. Such a desire can be found in many fields of knowledge. Physics searches for a unified field theory and a theory of everything while the *International Encyclopedia of Unified Science* had hoped for the same. However, it too fell on hard times when Thomas Kuhn, a member of its editorial group, argued that this was an impossible task by describing the history of science as a set of revolutions in the second book of volume 2.

Jean-François Lyotard's critique of the grand narratives or metanarratives that legitimated knowledge through an emancipation narrative (e.g., Marxism) or a salvation narrative (e.g., Christianity), or the progressive narrative (e.g., capitalism) has had a profound effect in educational curricular circles. It marked a turning point—some would say a “hermeneutic turn” to begin to interpret texts ideologically and to deconstruct their seeming unity. The claims to metatheory became suspicious because of their totalizing nature, which were propped up by some form of transcendent and universal truth. In curricular thought, this truth was especially damaging. Developmental theories that had universalistic overtones—such as Jean Piaget's schema for developmental cognition based on genetic epistemology—that is, on an inherent structure of the mind; Noam Chomsky's transformational generative grammar that claimed an innate universal grammar common to all languages; and Lawrence Kohlberg's stages of moral development—all underwent critique for their universal structuralist assertions. It was found that the Piagetian pattern simply replicated the logic necessary for the development of secularized capitalism, while Kohlberg's moral development was inherently gender biased. Chomsky's schema underwent revision in light of the Sapir-Worf hypothesis, which maintained a linguistic relativity; the grammatical categories of the language a person speaks is related to how that person behaves and understands the world. For curricular thought, these developments meant that the assurances of the linear way children developed their verbal, written, and mathematical skills and their moral growth could no longer be maintained. The developmental schemas began to decenter and unravel as curricular theory faced the questions of differences along sex, gender, ethnic, mental ability, and linguistic lines. Particularities began to multiply as metatheory began to topple.

Such a meltdown, however, was being recuperated to keep the system afloat at the same time that it appeared to be sinking. Modernist closed metatheories have evolved into postmodernist open metasystems with the same general claim that a comprehensive theory is still possible, but with a caveat attached. The teleological end game of universalistic closed systems that end with a final purpose or final cause have been replaced with

temporal open ones—the final cause is unknown. In other words, the stability of a system is now taken to be relative until the next change occurs. One might take Karl Popper's falsifiability thesis as one of the key conceptualizations toward open system thinking. Knowledge remains reliable until it begins to accumulate anomalies and is proven false by an observation or a physical experiment. The step beyond the Popperian gambit is to maintain a heuristic approach to knowledge in each situational domain of science through stochastic analysis. Ilya Prigogine's work on dissipative structures, complex systems, and irreversibility, which identify states of disequilibrium (popularized as chaos theory) and Bruno Latour's actor-network theory mark further advances in open-systems thought. Metatheory status is thus retained through the neologism of holism rather than the former metaphysical signifier wholism by forwarding the interconnectedness of systems, thereby the topology of spaces (the mapping of things together) has become increasingly important. Surface as opposed to depth is forwarded. Generally speaking, the poststructuralism of open-systems thinking has changed the image of thought concerning science from a set hierarchical order to an order that is more planar and horizontal where any one set of factors holding a particular space-time configuration in place is likely to change should the dynamics of the system change.

There was yet another development that took a turn away from any possible metatheoretical recuperation or reconciliation toward the ironic self-reflexivity of antinarrative structures, especially in postmodern literature that moved away from modernist metafiction, stressing the impossibility of referential affirmation that dominated realist fiction. In the philosophy of science the anarchism of Paul Feyerabend moved in the same direction, denying the existence of universal methodological rules. It is perhaps only in the areas of art and drama curricula that the possibility of this self-reflexive ironic stance could have been explored and given its full artistic potential.

Both complexity theory and actor-network theory, emerging from the sciences have been applied to social and educational theory, but not without criticism. Complexity theory has gained ground in mathematical education, while actor-network theory has been influential in science

education, maintaining that human activity needs to be understood in its wider ecological setting in the way human beings (as just another subsystem) are interacting with other various subsystems. Complexity theory has now become the new metatheory spreading into business organization, strategic management, organizational studies, and evolutionary theory where notions of genetic drift have introduced a random element into the selection process making the process much more rhizomatic and chaotic. In education, the mantra “learning to learn” is precisely such a direction based on neoliberal principles of development, which claims to meet individual needs. Even the orthodoxy of evangelicalism has been affected by these developments. The metasignifier *God* has been dropped and replaced with intelligent design. The Vatican’s position on unidentified flying objects has changed to one of acceptance and possibility on the premise that God may have created multiuniverses, thereby accommodating an unexplainable event.

The key criticism regarding the appropriation of complexity theory into education emerges in the notions of both reductionism and expansionism despite the apparent complexity. This complexity results in a paradox. The question is whether there is something about human beings that these complex biological models are not able to articulate. Within the actor–network interconnected chain, human beings remain the most powerful and ideologically driven, having the highest encephalization of all creatures. To what degree does anthropology, which attempts to grasp human behavior, including all its inhumanness, still remain a viable realm of research to sort out the charge of an anthropocentric bias? The neglect of the nonhuman world is what is at stake if research remains too insulated focusing only on humans. In this regard, the question of ethics has now replaced morals in search for a nonteleological human science that can still provide a direction for the future of the planet.

In brief, the emerging educational imagination that is embracing more and more poststructuralist and complexity theory drawn from science and capitalist forms of organization is constantly being contested to find a new potential direction by educators drawing on cultural studies. This direction has emerged as a countermetatheory to scientific complexity, repeating in a different form the rift in

modernism between *Naturwissenschaften* (i.e., natural sciences) and *Geisteswissenschaften* (i.e., humanities). Since the early 1980s, curriculum theory (roughly the so-called reconceptualist movement) in North America finds itself caught in the tension between enlightenment modernism with its notable signifiers of the disciplines, subject areas, and linear clock time versus the shift toward the open-systems of science and the humanities, which introduce a new conceptualization of time and space that can no longer be accommodated by the structure of public schooling. The introduction of cyberspace into the schools through the various technologies of computerization to individualize the curriculum through online services have abetted the change toward the complexity imagination spearheaded by globalized competition while neglecting difficult questions that surround issues of tradition, history, and existential questions that pertain simply to living.

The conflict surrounding the possibility of a metatheory comes down the inherited tension of what appears to be an irresolvable antinomy between the particular and the universal. The universal is what particular things have in common. Ernesto Laclau attempts to resolve this impossible gap by maintaining the possibility of a particular universal. Some particular becomes the placeholder for the universal for an undetermined duration of time providing that the inclusiveness of a democratic ideal is being maintained. Laclau is following suit that is common to open-systems thought, with other educators following his lead. However, such a general theory remains caught by Aristotelian thought and dialectical thinking as forms of representation. To say one loves everyone means there has to be the one exception whom one hates; otherwise, difference could not be established. Gilles Deleuze who dismisses this dialectical imagination as an inability to overcome representational thought offers a rather dramatic opposition to this quandary. Through immanent morphogenetic transformations, he proposes to recognize the singularity of difference, independent from concepts of sameness, identity, resemblance, similarity, or equivalence. Pure difference identifies uniqueness that is not a factor of negativity, or a negation of sameness, but affirms the actuality of existence.

## MIDDLE SCHOOL CURRICULUM

---

Curriculum for middle schools should be different from elementary and high school curriculum—as different as the developmental needs of 10- to 14-year-olds are from younger and older students. As young adolescents become more cognizant of the world around them and of their place in it, developmentally responsive forms of middle school curricula reflect that awareness. James Beane’s belief that middle school curricula should focus upon the questions and concerns that adolescents have about themselves and their surroundings exemplifies this notion. It is also important to recognize that one of the functions of middle level curricula should be to extend and build upon the skills that students learned in the elementary school. Finally, curricula in middle schools should deepen students’ understanding of the disciplines of knowledge while simultaneously demonstrating their connectedness.

The separate subject approach to curriculum—the most common arrangement at the secondary level—will not be addressed in this entry, even though it is found in most middle grades schools. It is important to differentiate between middle grades schools and middle schools. Middle schools are schools where the needs of young adolescents

are addressed by educators who implement middle-level philosophy and practices, including curriculum. Middle grades schools are simply places that house young adolescents. What follows are brief descriptions of curriculum planning options for middle schools. It is important to note that in actual classroom practice, one curricular form often contains components of the others.

### Curriculum Integration

Curriculum integration is a curriculum planning philosophy in which students and teachers coplan the curriculum based upon the intersections of the students’ shared personal and global concerns. Curriculum integration is founded on democratic principles as all students have an opportunity to participate in the planning process by submitting questions that they have about themselves and the world around them. By soliciting adolescents’ questions, teachers recognize their students as thoughtful, diverse, and complex individuals who are capable of asking meaningful questions that are both personally and socially relevant. Students and teachers select common questions and name the intersections or connections between these personal and social questions. The connections among the questions are used to create themes that act as organizing centers of the curriculum. Once themes are selected for study, the students and teachers coplan the activities and assessments for each unit.

Curriculum integration is a different way of thinking about curriculum planning, and it can be quite challenging to implement. Many teachers find it easier to let the textbook be the curriculum and have students read chapters, answer chapter review questions, and take photocopied exams than to plan units, activities, and assessments from scratch. The time it takes to gather resources, create lessons and projects, and then evaluate them is considerable. Teachers who use curriculum integration leave themselves open to criticism from colleagues, parents, and administrators as it is a planning philosophy that is often misunderstood. Many critics of curriculum integration mistakenly believe that state and national learning standards, the disciplines of knowledge, and important skills are deemphasized or even ignored. However, because the curriculum is based on the human concerns of young adolescents, the disciplines of

knowledge, and therefore the learning standards (which are drawn from the content and process knowledge of the disciplines) are inherently present in the curriculum. Therefore, teachers who plan curriculum using the human needs identified by young adolescents will create units whose contents are found within and draw upon the disciplines of knowledge.

An additional criticism of curriculum integration is that it will not adequately prepare students for their futures. Advocates of curriculum integration believe that education as preparation for the future is a simplistic notion at best. This belief is especially true for adolescents as they are in the process of building their identities, not determining what job they will have, although future employment is a concern of most young adolescents. By providing adolescents with the opportunity to address their concerns within the contexts and cultures of their lives, teachers are following John Dewey's belief that allowing children to explore in the present will prepare them for the future. For most adolescents, units planned through curriculum integration are rich and significant because they grow out of the concerns and issues that are relevant to their own lives.

### Multidisciplinary Curriculum

Another curriculum approach that is designed to correlate two or more subject areas is called the multidisciplinary approach. Multidisciplinary planning correlates two or more disciplines taught around a central theme. A simple example is that in some high schools, sophomores take world history and American literature. As juniors, they take American history and world literature. In a correlated curriculum, students would take world history and world literature one year, and American history and American literature the next year. Thus, two disciplines, history and language arts, are correlated in the sense that the major themes America and world are being taught simultaneously.

Students are rarely involved in planning a multidisciplinary unit, and there is no conscious effort made among the teachers to demonstrate how the disciplines are related. Furthermore, the content of the disciplines remains the same, only the order of what gets taught is altered. Therefore, a multidisciplinary unit is relatively easy to implement from

a planning perspective as it only requires that participating teachers agree to teach their respective content at the time that it relates to the chosen theme during the length of the unit. That said, gradewide or schoolwide multidisciplinary units are a bit more complex and require more careful planning as all of the teachers of one grade or school are involved in teaching one theme.

When compared to the separate subject approach to planning curriculum, multidisciplinary curriculum helps to unify the separate subjects thematically. A potential benefit of this unification is that students may begin to understand that the separate subjects are related to each other or at least appear to be less fragmented than they are in the separate subject approach. In addition, because the main theme is examined by connecting two or more subject areas, students may better understand the theme. Such units are usually fun for both students and staff and also have the potential to build community.

### Interdisciplinary Curriculum

Many educators use the terms *interdisciplinary* and *multidisciplinary* interchangeably. Interdisciplinary curriculum differs from multidisciplinary planning in that teachers deliberately make connections between two or more disciplines. One such attempt is called *fusion*. In fusion, the content from two or more disciplines is combined in order to study issues. For example, a course called Ethical Uses of Technology could combine content and processing skills from the disciplines of science, social studies, and language arts to examine the social benefits and problems with technological innovations. Another common arrangement, especially during the freshman year in high schools, is to combine language arts and social studies classes into a two-period block where students study historical or social issues while reading related literature.

In middle schools, interdisciplinary units involve interdisciplinary teams of teachers that plan a unit around a common theme. Unlike planning with multidisciplinary curriculum, teachers preparing an interdisciplinary unit use concepts or questions used to inform the theme, rather than directly linking separate subject matter to the theme. For example, an interdisciplinary unit about rainforests

could conceivably center on the following large concepts:

- locations and types,
- global ecological impact,
- inhabitants,
- advantages-disadvantages of development, and
- getting involved.

Once teachers identify the major concepts or questions that they want their students to address, they develop activities related to the concepts. These activities cut across discipline lines, making it possible for teachers to team teach and for students to work on the same project during block periods—periods in which they would normally be attending single-period classes in which the separate disciplines are taught.

It is important to note that not all disciplines make equal contributions in such units, and therefore, some teachers may be either teaching content in which they are not certified or may be teaching topics not connected to the unit. Sometimes, there is a danger of making connections that are not clearly connected to the unit. It is important for teachers to contribute to interdisciplinary units in ways that keep the integrity of the unit in tact. Trying to make artificial or forced connections can confuse students and frustrate teachers. At the completion of the unit, the teachers could decide on another theme, maybe one in which other disciplines play a more prominent role in an effort to provide a balance among the disciplines and to ensure that students receive instruction in the state-mandated content areas.

One of the advantages of interdisciplinary planning is that students are taught to see connections among the disciplines of knowledge. In successful units, students are heard to ask, “So are we doing math, science, or language arts?” when working on activities. Interdisciplinary units help students combine knowledge and skills from different fields in order to solve problems and answer questions, which mirrors the way adults use knowledge and skills. This type of planning allows teachers opportunities to team teach and plan together, valuable experiences for professional growth and rejuvenation.

On the down side, interdisciplinary units take a great deal of time to plan, making team planning time a virtual necessity. As school budgets shrink

and pressure to raise test scores increases, many middle grades schools are eliminating team planning time and replacing it with test prep periods or classes focusing on basic skills, making it difficult for teachers to find time to plan interdisciplinary units. In addition, students are rarely involved in the planning process, so the themes are based on teacher ideas of what students may find interesting. As in multidisciplinary planning, interdisciplinary curriculum is discipline based as opposed to student centered, yet most students develop a greater appreciation of how the disciplines of knowledge are interconnected.

### Standards-Based Planning

Given the increased attention to standards during the last two decades, it seems logical to plan curriculum by beginning with the required standards for middle grades students. In standards-based planning, teachers begin by selecting major topics or themes as organizing centers and then use the relevant standards as the content and processes of the unit. Unlike curriculum integration, unit topics are typically selected without student input and may or may not cut across the boundaries between the disciplines of knowledge. For example, a science teacher could select the solar system as her theme and teach all of the science standards connected to the study of outer space, the laws of matter and motion, and rocketry. By contrast, a four-person team could select the topic of wetlands, and each teacher could address the corresponding standards within their own discipline (multidisciplinary planning), or they could team teach and combine disciplines (interdisciplinary planning).

To be responsive to adolescent needs and concerns, teachers encourage students to ask questions about the essential concepts and to discuss related topics of interest that could lead to projects and activities. Soliciting student input fosters curriculum that has the potential to connect to the multiple cultures of young adolescents. When adolescents see their cultures represented in the curriculum and understand that their teachers are willing to make personal and curricular connections to their cultures, they are more likely to feel accepted at school.

After gathering input from the students, the teachers examine the types of skills that students

will need to acquire and apply while learning about the essential concepts of the unit. Teachers can also examine gaps that need to be filled in students' knowledge bases and skills and prepare lessons, activities, and assessments with the intention of filling those gaps.

The final steps in standards-based planning are to design activities that blend the essential concepts with the skills and determine how these activities will be assessed. Most middle-level learners prefer hands-on types of activities meaning that simulations, debates, skits, creating models, and various forms of cooperative learning appeal to most young adolescents, making authentic forms of assessment essential to standards-based planning.

An advantage of standards-based planning is that because the unit begins with the standards, teachers can defend what they are teaching to those who may have concerns about whether or not the curriculum is aligned to state, district, or national standards. For more democratically minded teachers, standards-based planning provides an opportunity to plan portions of the curriculum with the students. Doing so can allow kids to feel a sense of ownership and relevance in their learning that can lead to higher motivation and participation.

Ironically, the advantage of incorporating the standards can also be a drawback as, even though most standards are written broadly, there is no such being as a standard middle school student, as middle school philosophy emphasizes the unique aspects of each adolescent. An overreliance on standards can reduce curriculum into an exercise of preparing for standardized tests. Middle-level advocates caution educators about falling into a trap in which the curriculum becomes the standards. Such a message seems especially relevant to educators who may be tempted to skip the allowing-for-student-input step in the standards-based approach. Doing so ignores the unique and powerful sociocultural experiences that students bring to the classroom and also ignores a major part of who they are.

### Final Thoughts

Schools for young adolescents that either are middle schools, or are trying to become them, contain

teachers who make deliberate efforts to move away from the separate subject approach to curriculum planning. Such teachers attempt to provide students with learning experiences that are relevant and developmentally appropriate, and these efforts at planning curriculum are consistent with middle-level philosophy. In short, middle grades schools that continue to hang onto the separate subject approach are not middle schools, as they do not follow the kinds of curricula recommended by middle-level advocates.

## MIDDLE SCHOOL CURRICULUM, HISTORY OF

---

It is difficult to trace the history of middle school curriculum, for unlike other aspects of middle school practice and philosophy (e.g., interdisciplinary teaming, advisory programs, exploratory classes and projects, and flexible block scheduling), middle-level advocates have fallen short of creating and promoting a consistent and coherent form of middle-level curriculum. Although middle schools were created as a response to the perceived shortcomings of the junior high schools that preceded them (although junior highs continue to exist), middle schools have historically distinguished themselves by their administrative structures. Therefore, identifying a particular evolutionary path of a middle school curriculum is difficult at best. What is apparent is that a relatively small number of middle schools have been places where important departures from the dominant, high school-driven, separate-subject approach have occurred. Such departures have been consistent with the kinds of curricula advocated by middle level curriculum experts, but have not been adopted in most middle grades schools, which cannot be accurately labeled as middle schools. In addition, depending upon one's political views, such curricular options are often viewed as exemplary exceptions or rebellious realignments that ignore standards and rigor. For this and other reasons, the curricula that students experience in most middle grades schools continue to mirror high school curricula, in other words, a junior high school curriculum.

In attempting to trace a history of middle school curriculum, it is helpful to consider publications that have described or recommended curricula that embraced middle school philosophy and practice. For example, middle-level advocates have recommended developmentally appropriate curricula for middle schools that connect content across the different subject areas. The major implications for such curricula are that they can be organized around themes that young adolescents see as being connected to their own lives. There is a long, but relatively unknown, history of curricular forms that addressed the needs of the learners and moved away from the separate-subject approach.

The idea that curriculum should connect the disciplines and in addition connect to the prior experiences of learners, goes back at least 250 years ago to the Herbartians. The Herbartians were followers of the German philosopher and educator, Johann Friedrich Herbart, who believed in the importance of concentration centers.

In addition, the Herbartians promoted the notion that ontology recapitulates phylogeny, basically meaning that the way an individual developed followed the order of the historical development of mankind. In the early 1900s, this idea served as a catalyst to G. Stanley Hall and others to form the child study movement, which in part promoted curriculum based on the notion of cultural epochs.

Hall's work, which focused on the importance of studying children and how they developed, created the foundation for developmental theorists such as Jean Piaget, Erik Erickson, and Lev Vygotsky. Ultimately, the adoption and modification of Herbartian ideas led to curricula that connected disciplines thematically and recognized the importance of the prior experiences and the developmental needs of the learners.

The U.S. link to Herbart runs deep, for many progressive educators of the early 1900s were influenced either directly or indirectly by Herbartian thought. In terms of linking today's middle-level curriculum advocates to the past, some of the more important educators who were influenced by the Herbartians include John Dewey, William Heard Kilpatrick, and L. Thomas Hopkins. The curriculum of the Dewey-run Laboratory School of the University of Chicago shared interesting similarities with current forms of curriculum found within middle schools. Although there was little doubt that the notion of cultural epochs had an influence on Dewey's curriculum, his ideas included respect for the feelings and interests of the students, an emphasis on investigation and problem solving, and a desire to connect learning with social experiences.

Drawing significantly from Dewey, the work of Kilpatrick is important; he promoted the project method, a curricular innovation that engaged students in learning by creating projects that incorporated the disciplines of knowledge and solved problems.

Kilpatrick also suggested that the curriculum should be organized around children's purposes as

opposed to subject matter. In addition, he believed that, much like Dewey, education was life itself, not preparation for it. Kilpatrick and the project method became extremely popular, and along with the ideas of philosophically similar curriculum theorists, became one of the foundations for the core curriculum movement.

In part because of interest in core curriculum, by the late 1920s and early 1930s, the term *integration* was receiving considerable attention in curriculum matters. Hopkins was one of the first to promote curriculum planned by teachers and students that centered on experiences of the learners and problem solving. Although student-teacher coplanned curriculum was a significant departure from multidisciplinary and interdisciplinary arrangements, Hopkins's ideas were often misunderstood, leading to blurred conceptions of integration. The lack of clarity of what curriculum integration is continues to this day.

Many of the seminal ideas of Dewey, Kilpatrick, Hopkins, and several of their contemporaries can be found in the work of many current middle-level curriculum advocates who have suggested that middle school curriculum be integrated—addressing and using the concerns of young adolescents to democratically plan curriculum. Their work is also closely connected to two forms of core curriculum, structured and unstructured, that grew out of curriculum arrangements in a few schools who participated in the Eight Year Study. Basically, both types of curriculum involve students and teachers coplanning curriculum, but in structured core, teachers and other staff identify themes of study while in unstructured core the themes are constructed by negotiations between students and teachers.

Today, what passes for middle school curriculum varies considerably upon the commitment of schools to middle-level philosophy. It seems as if the majority of middle grades schools continue to use the separate subject approach to curriculum planning, while a smaller number of middle schools use approaches that are multidisciplinary, interdisciplinary, or integrated. Contrary to popular opinion, such curricula have a long, distinguished, and complicated history as reform movements distinct from the separate subject approach.

## MIEL, ALICE

---

Alice Miel (1906–1998) served as an educational leader during the 1940s to the 1970s and symbolized the classroom teacher-university scholar who brought the spirit and practices of progressive education to higher education. Her scholarship in the field of curriculum revolved around her dissertation, later published as *Changing the Curriculum*, and brought the basic themes of democracy and cooperation—reformulated and described as a social process—to all activities of education and schooling. Miel accepted important leadership roles at Teachers College and in ASCD (Association for Supervision and Curriculum Development) and later helped to form the World Council for Curriculum and Instruction. Her career represents a particular type of curriculum academic who sought to maintain the principles of progressive education during the 1950s and 1960s, a period that did not embrace progressive ideals.

Miel taught Latin and French in Michigan public schools from 1924 to 1942. When asked in 1987 to identify her most important educational

experiences, she mentioned teaching from 1930 to 1935 in the democratically administered school with G. Robert Koopman as principal and attending a 1935 Progressive Education Association workshop at Ohio State University where she met Laura Zirbes. Miel began doctoral studies at Teachers College in 1942 where Hollis Caswell, who had recently formed the first department of curriculum and teaching, served as her doctoral advisor. She remained at Teachers College as a professor of curriculum throughout her career, retiring in 1971 after having chaired the Department of Curriculum and Teaching from 1960 to 1967.

The significance of Miel's *Changing the Curriculum*, published in 1946, cannot be underestimated for the field of curriculum. As the Progressive Education Association was in decline and a new era of school consolidation was to begin throughout the United States, Miel wrote in opposition of what would become the standard curricular practices of the 1950s. She maintained that the curriculum should be seen as being in a constant state of change, and the intent of curriculum organization was not standardization and consolidation, but instead, a form of social change—that is, changing individuals' beliefs, attitudes, knowledge, and skills rather than merely changes in the configuration of course alignments and listings. She believed curriculum development and school experimentation would transform education at the district level; however, rather than using a simplistic structure for curriculum planning (such as the Tyler Rationale), Miel underscored the importance of the social process, constructive social purpose, democratic leadership, and cooperation and cooperative study. These terms, also drawn from the progressive classroom of the 1930s, blended the 1950s human relations movement with a dynamic conception of learning where many individuals—teachers, students, staff, administrators, parents, community members—were actively involved in the activities of the school. “Cooperating to learn and learning to cooperative” represented a motto that Miel believed would serve as an antidote to the standardization that was beginning to overtake the field of education and curriculum planning.

Greatly influenced by the Progressive Education Association's cooperative studies, Miel sought to

incorporate the principles of the progressive classroom—teacher–pupil planning and curricular experimentation—into the field of curriculum studies during a time of increased curricular standardization and the rise of the curriculum specialist-expert. She wrote specifically about the role of the curriculum expert-consultant in the democratic process of schooling, and while such titles created hierarchies in staff structures, she maintained that all educators should be viewed as experts, differing merely in degree and the kind of expertise (e.g., classroom teachers are experts by knowing particular children at particular stages of development). This belief would become especially important as school districts were beginning to call upon educational administrators to take on responsibilities as curriculum specialists. Although these curriculum specialists would have been armed with the Tyler Rationale, Miel reestablished the crucial role of classroom teachers and incorporated cooperation and human relations as a most important aspect of the social process of curriculum design and development.

Miel participated in other research projects and edited publications and ASCD yearbooks where she also served as president of ASCD and the factotum of the Professors of Curriculum. During the 1970s, she helped to found the World Council on Curriculum and Instruction, serving as executive secretary and later as president. This organization, a direct outgrowth of an ASCD commission, embraced many of the most fundamental beliefs of the social process as developed by Miel throughout her career.

Miel served as a doctoral advisor to well over 100 students during her years at Teachers College. One of her students and later close colleagues, Louise Berman, described Miel as a leader, chosen by others, who abdicated privileges of leadership to complete those necessary tasks and who contributed her own expertise while drawing upon and building the strengths of the group.

---

## MINDLESS CURRICULUM

---

The term *mindless curriculum* in curriculum studies, refers to policy and practice that instantiates curriculum without careful, reflective study, thought, or anticipation of consequences. Mindless curriculum is often reactive vis-à-vis social, political, and economic pressures and sometimes refers to deskilling teachers of their thoughtful propensities by teacher proofing the curriculum—that is, by telling local educators rules to follow rather than enabling them to exercise intelligent judgment. Mindless curriculum is critiqued in a widely touted study of schooling in the late 1960s by Charles Silberman, published as *Crisis in the Classroom* in 1971. Similarly, one can find criticism of mindlessness in John Goodlad's *A Study of Schooling*. In the main volume published from it, Goodlad depicts the status of schooling in the late 1970s and early 1980s in *A Place Called School*. These and many other studies commissioned to examine education in the United States have revealed and criticized a follow-the-rules mentality. The use of mindless to characterize a nonreflective, reactive tendency in school is ironic in view of the fact that schools were presumably created to teach students and thus society to be reflective. The term mindless may or may not be used, although the sentiment is often there.

This and contemporary exposes of schooling hearken back to the first such study in the era of curriculum development. Joseph Mayer Rice, a young pediatrician who actually sought progressive

tendencies in school practice, was commissioned by a journal called *The Forum* in the last decade of the 19th century. His explorations led him to decry the routine and lock-step character of schools and their mindless perpetuation of procedures. His reports were published in 1893 in a volume called *The Public School System of the United States* and contributed to his lack of faith in the creativity to be expected in schools. Thus, in 1913 he published a call for greater efficiency in school management under the title, *Scientific Management in Education*.

Many curriculum scholars today draw upon work of Paulo Freire who has often critiqued the dominant banking approach to curriculum, an approach which increases mindless practices. Freire, however, seeks a resolution in democratic involvement of all concerned rather than through increased efficiency and control. He advocates overcoming mindless curriculum through a problem-posing approach.

The central point for curriculum studies of the term mindless curriculum does not reside in the frequency of the term's use. Rather, it lies in the idea that unimaginative procedures govern an institution or school that is supposed to stimulate and release the human imagination.

## MIXED METHODS RESEARCH

---

Mixed methods came into emergence during the 1990s as a process of combining quantitative and qualitative approaches at different stages within a single research study. Known as the third paradigm in research methodology after traditional

quantitative and qualitative methods, mixed methods attempts to legitimate the use of multiple approaches in answering research questions. The use of mixed methods is particularly suitable for research in curriculum studies because it permits the exploration of complex instructional issues that do not lend themselves to numerical examination and interpretation. The use of mixed methods eschews the belief that researchers are constrained in their choices for approaching the study of phenomena, relegated to solely selecting either the quantitative or qualitative approach.

Qualitative methods rely primarily on the use of text to generate findings, whereas quantitative methods use numbers to conduct descriptive or inferential statistics. Just as qualitative and quantitative approaches have requirements for application, so does mixed methods. In mixed methods inquiry, methodological congruence must be maintained. As a result, all of the assumptions of applicable methods must be adhered to and the components of each method must be consistent. Thus, strategies cannot be applied, combined, and selected liberally. Researchers must identify the overt dominance of each in study. The continuum that describes the degree of mixture ranges from monomethod to fully mixed methods. The potential for mixing methods is large because for example, a researcher may locate an emergent design during a study dependent primarily on the information that emerges or on the conditions of the study. Rather than be limited by long-standing designs, the researcher has the opportunity to let the findings guide subsequent phases of the research study. In essence, the researcher is not restricted to selecting among a menu of pre-planned designs; instead, the researcher can create a design that is likely to answer his or her research questions.

### Types and Stages of Designs

Eight types of multimethod designs grounded in deductive and inductive theoretical approaches have been identified. Four designs, identified for the inductive theoretical approach, are described below.

1. QUAL + qual refers to the use of two qualitative methods used at the same time. One

method, qualitative, is dominant and is the basis for the whole project.

2. QUAL + qual refers to the use of two qualitative methods that are used sequentially in which one method, qualitative, is dominant.
3. QUAL + quant refers to the use of a qualitative and quantitative method used simultaneously where qualitative methods are dominate.
4. QUAL + quant refers to the use of a qualitative and quantitative method used sequentially where qualitative methods are dominate.

Four designs have been identified for the inductive theoretical approach.

5. QUAN + quan refers to the use of two quantitative methods that are used at the same time. One method, quantitative, is dominant and is the basis for the whole project.
6. QUAN + quan refers to the use of two quantitative methods used sequentially in which one method, quantitative, is dominant.
7. QUAN + qual refers to the use of a quantitative and qualitative method used simultaneously where quantitative methods are dominate.
8. QUAN + qual refers to the use of a quantitative and qualitative method used sequentially where quantitative methods are dominate.

Researchers have also emphasized the importance of considering the stage of the research process during which the integration of quantitative and qualitative data occurs. There are four points in the process in which integration can take place within the study: (1) the research questions, (2) data collection, (3) data analysis, or (4) interpretation. Although integration typically occurs during data analysis or in the interpretation stages, it may occur at multiple stages. For example, survey data that is both quantitative and qualitative might be integrated in the analysis stage by transforming qualitative data into scores that can be compared to the quantitative scores.

Seven data analysis stages have been described: (1) data reduction, (2) data display, (3) data transformation, (4) data correlation, (5) data consolidation, (6) data comparison, and (7) data integration.

In data reduction, qualitative and quantitative data are reduced to themes, descriptive statistics, factor, or cluster analysis. Data display refers to illustrating data. Qualitative data are represented pictorially, while quantitative data may be represented as tables or graphs. Data transformation refers to the conversion of data. For example, quantitative data are converted into narrative data (qualitized) that can be analyzed qualitatively, while qualitative data are converted into numerical codes (quantitized) that can be statistically analyzed. Qualitative and quantitative data are correlated with one another during data correlation. During the stage of consolidation, qualitative and quantitative data are combined to create a consolidated set of variables or data sets. Data comparison refers to comparing data from both approaches. During data integration, the quantitative and qualitative data are integrated into a whole or into two separate sets.

Assessing the trustworthiness of the qualitative and quantitative findings and consequent interpretations is conducted during the legitimation stage. Frameworks to assess the 50 potential sources of invalidity for the quantitative portion of the mixed methods at the stages of data collection, data analysis, and data interpretation have been created. Frameworks to assess the potential of 29 types of legitimation for the qualitative portion of the mixed methods have also been created. The latter can also be used to assess the legitimacy of the qualitative and quantitative components of the study, respectively.

### Foundations

The researcher must have solid understanding of both quantitative and qualitative approaches to conduct mixed methods studies. Quantitative research problems are generally confirmatory or outcome-based, while qualitative questions are typically process oriented, exploratory, descriptive, and/or centered on a phenomenon. Quantitative data collection methods include the use of instruments, observations, documents, scoring, close-ended processes, or predetermined hypotheses. Qualitative methods are interviews, observations, documents, audiovisuals, participant determined or open-ended processes, or text or image processes. Descriptive or inferential statistics are the

quantitative data analytical procedures, while thematic identification or the identification of the horizontal or vertical connections among themes or categories is commonplace in qualitative research.

One assumption underlying the use of mixed methods is that the use of qualitative or quantitative approaches simultaneously provides a better understanding of the research question than either method by itself. Also requisite to using mixed methods is that an integration of the findings and an explication of the linkage between what has been found through qualitative and quantitative findings must be provided. Utilizing the mixed methods approach to analyzing the data requires extensive time in collecting and analyzing data. Mixed methods may also be used when more data is needed to extend, elaborate on, or explain the findings from the first data set. For example, findings from a survey may be insufficient to explain reasons for participants' beliefs. Use of follow-up interviews with participants in a qualitative study may offer greater insight and more specific information than the statistical results provide.

### Example 1

An example of the use of a mixed methods design, qual + QUAN, exploratory, that was used to create instrument follows. In this study, researchers who were interested in measuring teachers' beliefs began their inquiry with qualitative methods. Their goal was to construct a quantitative instrument that was easily scored, practical, and readily interpretable. To develop a student-centered teachers' beliefs scale, the researchers initially created a list of items. Once the initial set of items was created, cognitive interviews, a focus group, and expert reviews were performed to improve item wording and eliminate items that were unclear or redundant. Next, a pilot test was performed to eliminate items with poor psychometric characteristics. The instrument was then taken by 445 individuals, preceding two types of analysis: confirmatory factor analysis of scores of the scale and the short form of the teachers' sense of efficacy and a structural equation model (SEM) evaluating the relationship between teacher self-efficacy and student-centered beliefs. The aim of analyses was to provide different sources of evidence of validity, following the validity taxonomy presented at the

Standards for Educational and Psychological Testing. Evidence of validity was obtained using a SEM about the expected relationship between student-centered beliefs and teacher self-efficacy. The SEM examined whether efficacy in student engagement, efficacy in instructional strategies, and efficacy in classroom management was related to student-centered beliefs. The hypothesis was that all of these factors significantly predicted student-centered beliefs. However, the hypothesis was partially accepted. The results indicated that efficacy in student engagement and efficacy in instructional strategies significantly predicted student-centered behaviors, but efficacy in classroom management did not. The analyses confirmed the unidimensionality of the construct of student-centered instructional beliefs.

### Strengths and Weaknesses of Research Approaches

Charles Teddlie and Abbas Tashakkori have postulated that use of a mixed methods approach can mitigate the disadvantages that using quantitative and qualitative methods have by themselves. For example, mixed methods studies offer insight from divergent points of view and also provide researchers with an opportunity to use supplemental research strategies. For example, researchers who use survey questionnaires to determine teachers' reported use of instructional strategies might also want to see if those findings are consistent with what instruction looks like in classrooms. The addition of this qualitative approach allows researchers to determine if the findings from the survey are supported or refuted by what they saw in the classroom. One of the strengths of mixed methods is that it lets researchers develop as comprehensive and complete investigation as they wish. A variety of data collection methods can be utilized within the same study including questionnaires, interviews, document analysis, focus groups, and observations. Depending upon where the integration takes place in the mixed method study, strengths and/or weaknesses of the methodology vary.

Both quantitative and qualitative approaches have costs and benefits. Among the potential costs of qualitative research is one frequently cited criticism—that the findings are not credible. Multiple

perspectives or opinions are likely to emerge within a data set; however, it is important to remember that these do not always constitute realities. They may constitute the subjective realities of particular individuals, but they are not necessarily representative of the totality of views among the study participants. Adequate rationales are needed to support researchers' findings; otherwise the veracity of the results may be called into question, or worse, remain unsubstantiated. Qualitative research does, however, offer a pluralist, contextualized point of view, although, funding agencies may view findings as too abstract and too general for application to specific contexts and individuals. Other weaknesses of qualitative research are that the findings typically cannot be generalized beyond the context where the study was conducted and that research using this approach is time consuming. Also some researchers have asserted that the results might mirror the researcher's beliefs instead of the realities or lived experiences of the participants. Thus, the uniqueness of the qualitative findings and the assertion that the results do not appear to produce immediate and practical results causes those from a techno-rationalist point of view to ask the following: For whom are these findings useful?

Quantitative research is not without its criticisms either. Typically, the results do not explain why and fail to constitute the participants' understanding or perspectives. However, quantitative research holds an appeal for many researchers who like its orderliness and efficiency. Data collection tends to be relatively quick, while the analysis is typically precise and much less time consuming compared to qualitative research. The results are independent of the researchers, and the findings can be generalized when the data are based on random samples of ample size. Moreover, quantitative findings tend to be seen as more credible by funding agencies and people in power.

Overall, the use of mixed methods provides greater diversity of divergent views. The usage of different designs, such as concurrent exploratory, concurrent explanatory, sequential exploratory, and sequential explanatory makes implementation and discussion of results easier. Mixed methods rely on the principle of complementarity. The findings that result from this approach may enhance the quality of inferences that are made at the end

of a series of phases or strands of research. However, as some researchers have pointed out, the difference in the methods themselves may account for the differences in the findings. Some critics claim that mixed methods research suffers from the cognitive information processing limitations of the observer.

### Example 2

Another example of a mixed methods study can be seen in the hypothetical investigation of a research question within the context of culturally appropriate practice. The researchers could ask the question, “Is there a relationship between the specific parenting proficiencies shared by African American parents in low-income families of academically successful children? And if so, what is the nature of that relationship?” Through the use of a mixed methods research design, researchers could explore the possible variables related to parent proficiencies that contextualize the lives of the participating parents. Using a dominant–less dominant (QUAN–qual) design in which the quantitative study is conducted first followed by the qualitative investigation, the researchers could run a statistical analysis of quantitative data from a preexisting data set to explore salient variables that could be explained in a follow-up ethnographic inquiry. Researchers could deepen their understanding of key concepts through direct contact with individuals via surveys, focus groups, and in-depth interviews. As such, the data analysis is likely to provide a more expansive view of significant constructs and lead researchers to new knowledge about African American parenting and its relationship to student achievement.

### Choosing a Research Method

The work of educational researchers focuses on providing clarity about issues of interest to educators, researchers, and the public. Within the scope of their work, there is room for several realities to be illustrated through their findings. To determine what form of inquiry is most appropriate to the research questions or what methods are likely to produce information, it is important to first ask what type of information is being asked for. The answer to this question might be that more than

one form of inquiry is needed. As researchers have pointed out, mixed methods research recognizes the importance of both traditional quantitative and qualitative research, and it offers a more powerful choice that lends itself to offering complete, useful, and balanced results.

## MODERNISM

---

Modernism, an umbrella word, covers the words modern, modernity, and even moderné. These words derive from the Latin *modo*, meaning just now. As just now, modernism, modern, and modernity all deal with the continually current, always on the cutting edge of the present. Their histories, though, stretch back many centuries, and thus, while continually in the present, modernism and its allied words have long pasts. It is the play of the past with the present that keeps modernism always on the edge of an emerging future. Modernism can be looked at linguistically, intellectually, socially or politically, and educationally. Each view gives modernism another layer of richness and presents to us a concept that at times is apart from current traditions and at other times is apart of current traditions. This interplay of apart from and apart of is what gives modernism its dynamism.

Linguistically, the modern is part of that tripartite division of languages into old, middle, modern. Modern language raises issues of what is

linguistically acceptable or not acceptable: street language, official language; native language, dominant language; phonetic spelling, authorized spelling. Intellectually, the modern is part of the historic breaking of thought into periods: premodern period, modern period, postmodern period. Each of these has its own way of thinking; its own episteme. By thought down by historical periods, the modern is frozen into a time period: approximately mid-16th to early-17th century (Copernican revolution) to the early- to mid-20th century (quantum revolution). Socially and politically, modernism goes back to the 17th-century “wars” between the ancients and the moderns—those of a classical (and conservative) bent as opposed to those of a newer and more liberal, scientific-mathematical bent. Educationally, modernism goes back to Peter Ramus (1515–1572), who first used the word *curriculum* in an educational sense. There is a family resemblance in the curricula forms and thoughts of Ramus, René Descartes, and Ralph Tyler. What Ramus founded in the mid-1500s has been with us for centuries as Stephen Triche and Douglas McKnight point out and occupies a prominent place in schools today. The Tyler Rationale can well be considered the epitome of modernist curricular design.

### History of Modernism

The modernist movement, in all its forms, can be bracketed in the time span between Copernicus’ positing of a sun-centered universe in the 16th century along with the scientific revolution this spawned and the quantum revolution of the 20th century. By the end of World War II (in the mid-1940s), modernism and all it stood for (including its progressive phase) had died. After WWII, the advanced industrial countries of the West, entered a new age, one Jean François Lyotard labeled postmodern. This new, computerized, information-dominated age both fascinated and frightened Lyotard.

Ramus’s work preceded, slightly, the scientific revolution spawned by Tycho Brahe, Johannes Kepler, and Galileo Galilei, all of whom accepted and advanced the astronomical work of Copernicus a century earlier. Together these movements—Ramism in education (with a special interest in curriculum) and the scientific revolution—ushered

in the modern age, one logically ordered, scientifically framed, Protestant in its values, commercial in its outlook. Prior to Ramus, education was a piecemeal affair, young children learning to read and write from dames (wives and mothers) and proceeding onto study as they wished with itinerant teachers. The church schools (i.e., Catholic) were a bit more formalized, with the Jesuits, in 1599—a half century after Ramus—producing their *ratio studiorum* (i.e., plan of study). Ramus, a Catholic of Protestant persuasion—a persuasion for which he (literally) lost his head in the St. Bartholomew’s Day Massacre in 1572 when students broke into his University of Paris rooms and severing his head from his body, threw the former out the window—was a professor and schoolmaster. As a schoolmaster, he trained boys ages 8 to 16 for the university; as a professor, he organized the knowledge he taught the boys into what, borrowing from John Calvin (*curriculum vita* or path of life), he called a curriculum. The word *curriculum* (Latin for circular path) was used by Ramus to designate not a racetrack, but rather a course of study to follow. He laid out this path in a linear, hierarchal, and orderly manner (actually a visual chart) beginning with the most general (i.e., that which came first) and proceeding in a step-by-step pattern. Ramus’s charts, much akin to the bracketing done in current tennis, golf, or basketball tournaments (or to university or corporate line and flow charts from presidents through vice presidents to deans or directors to faculty or employees), were usually dichotomized into splits or two or three. Thus, knowledge to be taught would be split into the trivium and quadrivium with the trivium split into grammar, logic, and rhetoric and the quadrivium split into arithmetic, geometry, music and ethics, and physics and astronomy. These individual subjects would again be split into subparts: arithmetic would be split into addition, subtraction, multiplication, division. Addition would then be split into whole numbers, positive and negative integers, fractions, and so on. Subtraction, multiplication, and division would follow the same branching (ramification). This charting of knowledge into a visual representation (logical, orderly, hierarchal) was a great advance on previous, disorganized forms of representation, either woodcuts—the most famous of which was the tower of knowledge with a key (the alphabet)

unlocking the basement door and the flag of philosophy fluttering from the top turret—or just long memory lists given in no particular order. Ramus's sequencing of knowledge in a logical form became popular with the rising merchant class—it was both orderly and efficient. As an organized way to study, curriculum entered the protestant universities of Leyden and Glasgow in the early 1600s.

Along with organizing knowledge in a textbook manner, Ramus made a decision that has influenced Western teaching ever since: Knowledge should be taught (via direct instruction) in the same way he organized it. Today, reading that follows the phonetic method is a carryover from Ramus's sense of logic. Whole word or sight recognition methods are often considered illogical: They do not have a definite pattern. Ramus's sense of pattern—simple in its sense of order—appealed immensely to the Puritans and their simple piety. They quickly adopted Ramus's method of organizing and his logic, based on there being one and only one true (or best) way. In Colonial America in the late 17th and early 18th centuries, Ramism—the product of that great scholar and blessed martyr—and all it stood for permeated virtually every thesis done at Harvard College.

Ramus's method of organizing knowledge (a curriculum)—while attacked, often quite mercilessly (common at the time), as being too simple, starting with the most general or well known and proceeding reductively down to the particular—was part of the larger and more general methodization movement that swept Northern Europe and Colonial America in the 17th and 18th centuries. Francis Bacon, John Bunyan, Johann Comenius, Descartes, Gottfried von Leibniz (not to forget Isaac Newton, alchemist and scientist) were all caught up in this movement. It has been said that by the end of the 17th century, Protestantism had its answer to Catholicism's spirit: method. Method—scientific, rational, normed—captured the allegiance of the new men (engineers, builders, industrialists) of the 18th and 19th centuries. Frederick Taylor brought it to the forefront in his time and motion studies in the late 19th and early 20th century. Efficiency and scientific management became bywords of the times, including the organization of school curricula. Tyler's *Basic Principles of Curriculum*—(pre)planned, sequentially ordered, scientifically assessed—comes from this lineage,

and his four steps for developing a good curriculum has a strong resemblance to Descartes four steps in his *Discourse on Method for Seeking Right Reason and Truth in the Sciences*.

Another aspect of modernism came from the 17th and 18th centuries, war between the ancients and the moderns. This war—represented in the writings of Giambattista Vico (1668–1744)—was over who would control university curricula. The ancients (scholastics, rhetoricians, classicists) favored learning the classical languages, in particular the grand rhetoric of Cicero. The moderns (the new natural philosophers) favored contemporary (i.e., now) scientific, rational, and mathematical learning and the use of vernacular language. This classical or modern distinction carried well into the 19th century, particularly in the curricula of British schools, some favoring the classics and ancient languages, others favoring the sciences, mathematics, and vernacular language. In the United States, Robert Hutchins's Great Books program and the curriculum at the colleges he founded in Santa Fe, New Mexico, and Annapolis, Maryland, carry vestiges of this classicism.

Over time, the moderns with their success in medicine and astronomical predictions and their practical appeal to a rising commercial class of merchants (where employment not heredity were determiners of rank) became dominant. Their values—practical, bourgeois, progressive—became the traditional values of society. Social power shifted from those connected with the church or aristocracy to those prominent in commerce and industry. Education (and the curricula in schools) took on a practical hue. No longer was education restricted to the elite few, nor was it purely for the enjoyment of study. More and more education became associated with schooling adopting a practical, useful bent. One became schooled for commerce, industry, a trade, or profession. In this new industrial (modern) age, the engineers, planners, and builders believed they would tame and improve the ways of nature—in genetic breeding and in human society. The notion of being civilized took on a definite White, Anglo-Saxon, male flavor. And with such civilizing came the moral duty of those civilized to civilize or at least to control and lead those not civilized.

Modernism now took a twist; it became the tradition and as such, spurred a counter (avant-garde) movement. This countermovement, led by the

artistic, flamboyant avant-garde—in music, dance, painting, drama, literature—along with some intellectuals on the political fringe, played modernism off against itself. In a sense, modernism now defined itself (as tradition) and transcended itself. The avant-garde, favoring the cutting edge of the just now, an edge continually reforming, reframing, and redefining itself, took the social traditionalists (the bourgeoisie) as their enemy. They wished to shock the sensibilities of those possessing traditional authority, those who saw employment and productivity as virtues, indeed as the holy grail to lead all to a life of progress. As brilliant (and still brilliant) as are the works of Pablo Picasso, Sergei Diaghilev, Igor Stravinsky, Frank Lloyd Wright, and James Joyce (to name but a few), the modernists were caught by that which they attacked. As avant-garde, they needed bourgeois tradition as a foil for their creativity. With the advent of pop culture in the 1950s, this form of modernism died—the traditional versus avant-garde distinction disappeared. This particular modernist tradition had a relatively short life of about one century—from the mid-1800s to the mid-1900s.

During this century though, modernism in both its scientific form and artistic form dominated intellectual thought and brought with it great creativity. Scientific creativity and artistic creativity not only existed side by side, but also actually played off one another. Curriculum was mostly influenced by science, which in its ideological form became scientism, a grand narrative answering all needs. In many ways, Frederick Taylor's work in industry (his time and motion studies on worker productivity) became the holy grail of modern progress. Through scientific management—workers separated from and taking orders from managers—production increased as did worker pay (albeit to a far lesser degree). Progress—defined in terms of efficiency and productivity—in the early decades of the 20th century, seemed not only assured, but also inevitable. Into this rich, industrial, milieu of efficiency through tight control and productive progress through efficiency, the Progressive Education Association (PEA) was born (1919). The PEA was part of the broad political and social progressive movement, a modernist movement, which captured the hearts and minds of

many Americans from the 1890s through the 1940s. By the end of World War II, though, progressivism and the PEA, and indeed modernism itself, were dead.

After World War II, pop culture became so diffuse (and indeed so common) that avant-garde no longer was a meaningful term. The avant-garde versus traditional distinction lost its sense of definition; it referred to a time past not a time present (i.e., just now). Scientific thinking now infused with the quantum became less certain and more problematic-probabilistic, rational reason was beginning to be seen as only one form of reason, educational research became infused with the qualitative and anthropological, and society started on the road to integration. A new, computerized world came into being. No longer was there one dominant (traditional, unified, correct, all encompassing) culture; a variety of “posts”—postmodern, poststructural, postcolonial, postpatriarchal, and even posthuman—emerged. All these posts challenged the basic metanarrative foundation of modernism. In advanced, Western, industrial societies capital was replaced by knowledge as the currency of the realm. The current information age came into being. Nothing captures the drama and excitement around the creation of this information age better than the Macy Conferences, held in New York City in the years 1946 to 1953. At the conferences were gathered some of the brightest mathematicians, computer designers, psychologists, psychiatrists, and anthropologists of the time. Information theory, communication theory, cybernetics, and insights into learning and mental disease came from these conferences. The systems foundations for the new sciences of chaos and complexity were also laid at this conference. A new paradigm began to emerge, a paradigm heavily tilted towards and influenced by technology, the new sciences, and the coming to age of biology. The arts—literature, music, drama, painting, architecture—which had been so dramatic, indeed flamboyant, a generation before, were not part of the Macy Conferences, nor were they part of the measured world, which defined the mathematical, scientific, and rational aspect, which so engulfed intellectual thought at that time (and continues to do so today). Scientific rationality has become the dominant mode of thought; it has taken on the power Lyotard feared it would. This rationality,

devoid of personal feeling, artistic expression, or aesthetic culture, has become paradigmatic. For Lyotard, we need to eschew this mode of thought and be incredulous toward it, especially its universalizing tendency to see all through one lens. Instead, we need to look at the now as an ongoing (re)creation.

Interestingly, Lyotard's use of the term postmodern actually refers, not to a time after modernism, but to a modernism that is continually rewriting itself. Viewing modernity as an act of rewriting is Lyotard's hope for the future, a dynamic (now) modernism, continually on the cutting edge of the current epoch. A postmodernism separate from the modern, which freezes the modern in a particular time period, is a postmodern that terrorizes all that does not fit into one, universalizing, grand narrative. For Lyotard, the postmodern (in its best sense) is really a dynamic form of the modern; it is a modern that is always just now; it is a modern that is situated in the local, a modern which interplays with the traditional and accepted, but always moves beyond these. In a real sense, it is postmodern.

### The Teacher's Role in a Modern and Postmodern Frame

Every period or movement has its own ethos, and often that ethos is recognized after the period or movement has passed. To take this statement at face value, though, is too simple, for in many ways, a period or movement does not pass on as much as it is subsumed or extended by the next movement. In short, there is a flow between movements, a flow which we break into linear order for our own purposes. Such linearization is far more common in the English speaking world than in the French speaking world. French intellectual thought is more fluid, integrative, relational, as is evidenced by a host of French "post" writers, often labeled poststructuralists. Hélène Cixous, Gilles Deleuze, Jacques Derrida, Julia Kristeva, Bruno LaTour, and Michel Serres are but a few of those who point out this relationship between language and thought. These authors provide a fine counterpoint to the analytic-linear style of analysis so common in modernist Anglo-American philosophy.

The ethos of modernism is complex. It is universalizing, totalizing, and indicative of the grand narratives on which Lyotard declared war. This modernist thrust, born from the union of both the scientific revolution and the Protestant burghers (the gentlemen of commerce) of the rapidly expanding towns and cities in Northern Europe, with vestiges of the Enlightenment (particularly its commitment to reason), created an ethos the modernés (the avant-garde artists) were to challenge. Without the straight-jacket of this form of modernity, though, the avant-garde artists would not have been so creative. So, too, in a sense, without the work Tyler put out for others to pick up as a rationale, the reconceptualist movement would have taken a different form.

The point-counterpoint play of modernism as it struggled both to define and transcend itself has yet to emerge in the curriculum field. Certainly no longer moribund, this field is still caught in either-or dichotomies rather than point-counterpoint interplays. In short, the field is not yet postmodern.

The hyphen in post-modern, to signify this interplay, is similar to Lyotard's use of *re* in his reflection on his own statements about the postmodern. A few years after writing *The Postmodern Condition*, Lyotard suggested the phrase (re)writing as a useful addenda. In this text, he talks about the modern, the just now, always reflecting back on itself. Such a recursing, so important to chaos and complexity theories, keeps the modern always on the cutting edge, on the cusp of change. The postmodern (or better post-modern) is but a phase in this process of modernity continually (re)writing itself. The teacher who is able to envision the now as a continual process, not as a set period in time, who is not placed in a straight-jacket by the prevailing culture of the time, who is able to bring the yet-to-be into focus, should be able to deal with curricula issues in a way in which the history, contemporariness, and emerging possibilities of a field flow together in a continually recursive manner. This challenge is modernism's greatest legacy to contemporary curriculumists.

## MONTESSORI CURRICULUM

---

The Montessori curriculum is based upon the work of Maria Montessori (1870–1952), an Italian educator, educational theorist, and student of child development who contributed enormously to the field of curriculum studies. She developed and promoted the enduring Montessori method of schooling and teaching. At the core of her method was an emphasis on the child’s experience in a learning environment that was based both on the student’s interests and was rigorously structured. The method remains popular in many parts of the world today and represents a child-centered curriculum with self-directed activities and specified areas of learning.

Montessori had an abiding respect for the competence of children, and that fact was served as an underpinning of her child-centered approach to the curriculum. In her approach, students are taught to develop skills and acquire knowledge at an individualized, self-guided pace. Within the Montessori educational approach, children were, first and foremost, the center of intense study by the teacher, who made rigorous observations of them in their natural environments. It was then the role of the

teacher—who no longer occupied center stage in the schoolroom—to structure the school environment in a manner that aroused the interest of students through their senses. Structuring the school environment around the interests of the students would lead to the restructuring of the school environment in a manner conducive to exercises in which students engaged independently in practicing the activities of daily living. The teacher would guide students through activities that, on the one hand, were personally and practically meaningful to them while, on the other, engaging them in the use of their powers of observation and reflection.

Montessori’s child-centered educational strategies owed much to the previous work of Frederick Froebel, especially the notion of instructive play as described in his *The Education of Man*. Other influences on her method came from Jean-Jacques Rousseau, Johann Pestalozzi, and Edouard Seguin. Moreover, her emphasis on the interactions between the child and his or her environment also accorded somewhat with the progressive curriculum platforms of U.S. pragmatist educationists such as John Dewey. Other emphases shared by Montessori and informal educators included the placing of the teacher on the sidelines of an educational process that sought to foster self-realization and self-determination in the students. The most useful and significant learning was seen to occur when all senses of the students were fully engaged in the experience of living.

For Montessori, as for many other progressive and informal educationists, the result of this process would also include the development of responsibility, self-respect, and respect for others. This Montessorian emphasis on attitudes and habits of mind may be seen as presaging John Dewey’s focus on the fostering of a democratic mind-set in children and adolescents. The Montessori curriculum revolved around specific areas, including activities of practical life, sensorial experiences, mathematics, language and literacy, and a general cultural realm to include arts and sciences and geography and history.

Although Montessori passed away in the Netherlands in 1952, the Montessori method is still very much alive. Although Montessorian purists have sometimes decried the modern modifications of the method within the operational curriculum of some schools, most of the central characteristics

discussed above have endured. Her groundbreaking approach to the place of children in the curriculum is still widely visible today inside and outside of Montessori schools, especially in the early grades.

## MORIBUND CURRICULUM FIELD, THE

---

Declared first by Joseph Schwab in 1969 and reiterated by Dwayne Huebner in 1975, this assessment of the state of the field points up the intensity of the crisis it underwent following the 1957 launching of the first man-made satellite, *Sputnik*, by the USSR. General agreement exists that Schwab's 1969 pronouncement coincided with the emergence of a paradigm shift in curriculum studies, usually referred to as a reconceptualization or renaissance of the field. The effect was to change the field's focus from curriculum development to a scholarly effort to understand curriculum from a wide variety of perspectives. The degree of influence Schwab exerted on that shift, however, has been disputed.

Following *Sputnik*, amidst grand rhetoric of concern for education's role in the national security, the federal government allocated massive amounts of federal funds for curriculum reform through such legislation as the 1958 National Defense Education Act and the 1965 Elementary and Secondary Education Act. A fundamental reorientation of curriculum research occurred as the monies went mainly to discipline-based scholars, especially those in math, sciences, and foreign languages. The focus of improvement shifted to individual school subjects rather than to various theories of curricular program design. In addition, philanthropic organizations such as the Ford Foundation awarded grants

for educational research to social scientists outside schools of education, thrusting the work of curriculum professors further to the margins. All of this came on the heels of a series of critiques of public schools and education professors by arts and sciences scholars during the 1950s. In addition to these external pressures, discontent had already been building within the field in regard to the venerated Tyler Rationale as an adequate basis for thinking about curriculum work. All of these circumstances helped drive the field into the state that Schwab referred to as moribund.

Although Schwab believed the condition to be one that occurs within all fields periodically, he diagnosed the problem in this case as an unhealthy reliance upon the theoretic, in an Aristotelian sense, evidenced in part by the post-*Sputnik* emphasis upon the technical, behavioristic research paradigm. As additional symptoms he also noted several types of flight, including a flight to experts in other fields for solutions to problems, very likely a reference to the post-*Sputnik* transfer of curriculum responsibilities to subject matter specialists and educational psychologists.

To restore vitality to the field, he prescribed a new approach, focused on the practical, but not averse to theory. To the contrary, he believed a strong theoretical background was necessary to select and craft various theoretical perspectives to unique problem situations. He envisioned school-based teams engaged in deliberation, identifying and exploring solutions to curricular dilemmas. The emphasis would be on gradual curriculum improvement, as opposed to the broad-based school or social change that had been sought by many progressives. Teams would be composed of school faculty, subject matter specialists, and social scientists and would be chaired by a curriculum specialist. The role of curriculum professors would be to prepare the curriculum specialist in the practical skills of persuasion and deliberation and the scholarly skills of accessing and utilizing the latest research on curricular practices, the behavioral sciences, and academic subjects in the school curricular program. For their role, Schwab advised curriculum professors to become more intellectual; to read broadly on U.S. government, life, and society; and to take up the mantle of the critical essayist, commenting on current issues as they related to education.

Philip Jackson pointed to the tension in Schwab's advice for professors to focus more on the practical, while also exhorting them to become more intellectual. He noted the similarity between the description of Schwab's academic role for professors and the subsequent work of scholars of the reconceptualization. However, many reconceptualist scholars credit other bodies of work as their inspiration, most notably those of James Macdonald, Dwayne Huebner, and Maxine Greene. Scholars of the reconceptualist vein celebrate the post-1969 renaissance of the field, while curricularists who remain focused on curriculum development are less optimistic about its revitalization, citing a lack of engagement with the schools and Schwab's original critique of an overreliance on the theoretic.

## MULTICULTURAL CURRICULUM

---

At its most basic level, multicultural curriculum involves issues similar to those of concern in any curriculum development. They are what knowledge is of greatest worth, to whom and why, and how can it be best organized to be delivered most effectively to students. These apparently straightforward questions become complex, commanding, and unique to multicultural education when they are applied to deciding which dimensions of diversity are to be the units of emphasis and how the studies are to be conducted. They are challenging decisions to make for several reasons. First, all possible forms of diversity cannot be included in any given curriculum. Second, of the many things that can and should be taught about the explicitly

declared diversities of study, which are most important, and how will these determinations be made? Third, should the curriculum focus on cognitive content only, or are other forms of knowing equally important, such as thinking, feeling, valuing, acting, reflecting, and transforming? A fourth key curricular issue is whether multicultural education should be an independent enterprise, an integral part of all other subjects and skills taught to students, or both. Educators do not have to operate alone in answering these questions. Much assistance is available from research and scholarship, including conceptual principles and possibilities for actual practice for creating multicultural curriculum.

### Multicultural Curriculum Principles

Invariably, curriculum is created in and reflects multiple layers of contextual influences. This reality defies the hopes of some educators that a single multicultural curriculum can be created and transported across all school settings and student populations. Scholars may not speak in a single nomenclature (nor should they be expected to do so), but there is a high level of agreement among them about why multicultural education is important, what are its fundamental substantive components, and how it should be implemented. Together these ideas constitute the foundations for curriculum development for and about ethnic, racial, and cultural diversity.

The conceptual and ideological parameters of multicultural education provide baselines for creating curriculum rationales, goals, and objectives, content, learning experiences, and assessment procedures for students and teachers. One of these emphasizes ethnic, racial, and cultural diversity within the United States, as opposed to global or international settings. This initiative originally grew out of concerns about discrimination and oppression against groups of color in U.S. society and the inequities they suffer in educational institutions. Some advocates extend these constituent concerns to other dimensions of diversity (such as gender, social class, and sexual orientation), but not as the expense of or as proxies for race and ethnicity, and locations of analysis (national and global). As groups, African, Latino, Native, Southeast Asian, and Pacific Islander Americans

have the lowest records of school performance, regardless of the achievement measures or indicators used, level of schooling, or social class of students. Proponents of multicultural education suggest that they are more a function of educational programs, policies, and practices that ignore or demean the cultures, heritages, experiences, and perspectives of ethnically and racially diverse groups than the intellectual abilities, interests, and aspirations of individual students. Interventions that counter these attitudes and related practices may be the best courses of action to pursue for closing achievement gaps among students from majority and underrepresented groups. This is a logical premise to make because race, ethnicity, class, culture, and education are deeply interconnected.

A second major ideological principle of multicultural education is that it is more than a cognitive endeavor. Although all students in all educational settings and levels of learning need to acquire a greater depth and accuracy of knowledge about the wide variety of ethnic and cultural groups that comprise the United States, this is not enough. Racial attitudes, values, beliefs, and behaviors of individuals and institutions in the past, present, and future should be analyzed and modified. Combating racism requires moral convictions and political actions along with more accurate knowledge. So does empowering students to contribute to constructing a society that is more culturally inclusive and socially, politically, and economically egalitarian. Therefore, the goals of multicultural education include both what to teach about ethnic, racial, and cultural diversity and how to teach ethnically diverse students more effectively through cultural responsiveness. They are deeply interconnected, and it is counterproductive to argue for one instead of the other. In creating multicultural curriculum, these interrelationships should be kept in mind, along with the need to provide multilayered and culturally appropriate learning experiences for ethnically and racially diverse student across them. When implemented, whether separately and in concert with each other, they improve the performance of underachieving students of color on multiple levels—social, personal, cultural, psychological, emotional, political, and academic.

Curricular concerns about ethnic, cultural, and racial diversity are more complex than the

presentation of factual information about minority and marginalized groups. They involve deeply entangled moral dilemmas, correcting negative attitudes and beliefs, transformative insights and actions, and the redistributions of power and privilege. They affect all people in some way or another and are, therefore, appropriate for all students, school settings, and subjects, but not in identical ways, meaning that critical features of multicultural curriculum are using multiple perspectives and different ways of knowing in examining ethnic, racial, and cultural diversity.

Another aspect of multicultural education that has strong implications for curriculum creation is its interdisciplinary nature. None of its components and concerns can be analyzed and understood sufficiently through the lens of a single discipline. They demand the knowledge, insights, and methodologies derived from many different bodies of scholarship and styles of teaching and learning. For example, if educators are to establish viable foundations for understanding the performance patterns of students of color over time, they need to analyze them from the vantage points of history, psychology, sociology, anthropology, economics, and pedagogy, all within the contexts of ethnic and cultural diversity. Similarly, students can learn better the nature and effects of racial prejudices and oppression, how to be social justice activists, and function more effectively in cross-cultural encounters by reading scholarly books and culturally expressive literature; engaging in analytical discussions and critical self-reflections; listening to different genres of social commentary music; examining demographics on racial profiling; observing the social and political behaviors of people in different ethnic groups and positions of power; participating in cultural events; compiling and analyzing personal narratives; and forming coalitions with ethnically diverse individuals and groups for social, cultural, and political reform. The idea is that cultural diversity is a dynamic and complex phenomenon and understanding it authentically requires varied approaches to teaching and learning.

One way to actualize multicultural education in practice is to make it an integral part of the curriculum of everything else that is taught to students, whether that is reading, writing, math, science, citizenship, critical thinking, or computer

technology. Proponents note that this approach is pragmatically feasible and pedagogically sound. K–12 schools are not likely to teach multicultural education as a separate subject, even though some colleges will. The latter is a greater possibility because studying discrete disciplines fits into the prevailing conventions of how college curricula are organized and implemented. Although it is useful to think conceptually and theoretically about multicultural curriculum as a separate entity or artifact, for classroom practice it is more reasonable to think of it as a component of or presence in other learning plans and instructional actions. Therefore, it has high instrumental value in that it improves the quality and effects of all learning opportunities and outcomes for ethnically diverse students.

If educational institutions are committed genuinely to teaching students historical realities and cultural truths, then the content taught within and through the various subjects needs to be culturally diverse to reflect the plurality of contributions that formed and continue to shape them. Compelling evidence demonstrates that the United States is not a European American–only construction. Rather, it is and always has been a pluralistic composite, a synergy of the contributions of many different ethnic groups and individuals. What the country currently is, as well as its potential to become, are direct reflections of its ethnic, racial, and cultural diversity. It is our reality, our potentiality, and our strength. This is one of the key messages multicultural curriculum conveys to students, and it is best done by integrating information about ethnic and cultural diversity into all subjects and skills taught for all students, at all times, instead of restricting it to isolated lessons, units, or courses for select student populations and special occasions.

Desirable multicultural curriculum integration is not easy to accomplish. The challenge involves more than merely adding appropriate information about ethnically diverse contributions, cultures, and experiences into existing curricula. Sometimes entire curricular frameworks and their underlying assumptions, values, customs, traditions, and claims of truth may need to be challenged and changed. A case in point is the pathological orientation mainstream society has displayed toward groups of color as dependent and universally powerless. It needs to be replaced with conceptions (and related instructional actions) of power and

agency as being contextual and situational. Viewing power and agency in this way means that the most powerless groups in mainstream society may be quite powerful, imaginative, creative, and resourceful within their own cultural contexts and from insiders' marginality perspectives. Certainly, some of the most stimulating and successful social justice momentum has come from the leadership of ethnic individuals on the margins of mainstream society, such as Martin Luther King, Jr., Harriet Tubman, Caesar Chavez, and the civil rights movements of various ethnic groups of color over time. These emphases fulfill other intentions of multicultural curricula including developing positive ethnic identities, cultural pride, and personal efficacy; closer aligning the realities of U.S. society with its democratic ideals; and functioning more effectively in different cultural systems and relationships.

Multicultural curriculum integration does not exclude the possibility of, or the necessity for, some discrete studies of ethnic and cultural diversity as well. But these should be complements to general, wide scale, integrated learning experiences, not in lieu of them. Thus, courses in Latino politics, African American music, and Asian American psychology, and college majors in multicultural education provide opportunities for interested students to study these topics in greater detail than what they might acquire from the multicultural contributions woven into other subjects and pedagogies.

### Translating Principles to Practice

Theory suggests that content about ethnic and cultural diversity should be inserted everywhere and all the time throughout the educational enterprise. However, these proposals do not provide any practical guidance for how to actually do what is being suggested. The absence of this assistance reduces the likelihood that educators will embrace and act on what are otherwise powerful ideas. To minimize this possibility, some suggestions from multicultural education advocates are now presented for translating general multicultural curriculum principles into actual practices.

Educators should develop strategic plans for incorporating ethnic and cultural diversity into teaching and learning on a regular and routine basis. An important part of this planning is realizing that

all subjects cannot be multiculturalized at the same time, in the same way, or at the same rate. Some subjects and learning locations are initially more amenable to accommodating cultural diversity than others. Consequently, priorities need to be established, and curriculum reform plans made that allow for variability within the established disciplinary boundaries of multicultural education and developmental progression across subjects, grades, and learning settings over specified periods of time. These changes do not have to be linear in that they begin with the lower grades and basic subjects or skills and then proceed sequentially to the more advanced ones. Some multicultural curriculum interventions may begin in Grade 5, others in Grade 2, and move up, down, or sideways until all subjects in all grades are impacted. One high school could start integrating multicultural education with 10th-grade English and move from there to 12th-grade social studies, followed by 9th-grade mathematics. Creating multicultural curriculum also involves multiethnic representation, or including different kinds of significant information about the histories, heritages, cultures, experiences, contributions, challenges, and possibilities of a wide variety of ethnic groups in all teaching and learning encounters.

More pragmatic suggestions for accomplishing these general principles in actual multicultural curricula are as follows:

- Place information about ethnic and cultural diversity into the core components of high status, high stakes subjects, skills, and learning processes routinely taught in schools, such as reading, math, science, critical thinking, and test taking.
- Include information about a wide range of individuals, events, perspectives, and experiences within and among ethnic groups, locally, regionally, and nationally.
- Use specific cultural content, examples, perspectives, and experiences of diverse ethnic groups to illustrate general academic concepts, principles, ideas, and skills, and for students to practice and demonstrate mastery of them. For instance, use African, Asian, Latino, Native, and European American novels to illustrate literary techniques or ethnic residential patterns to teach geographic concepts.
- Diversify the types of individuals, information, and experiences used to represent ethnic groups to prevent dependence on the overexposed, exceptional few who have become common stocks-in-trade in teaching cultural diversity and to avoid ethnic type casting. Hence, Asian Americans should not always be presented as high achievers in mathematics and science, African Americans as pop culture singers and professional athletes, and Mexican Americans as immigrants and migrant farmworkers.
- Avoid placing different ethnic groups in competition with each other by emphasizing various perspectives on common themes. For example, examining the different ways African, Asian, Native, Latino, and European Americans have engaged in social justice struggles over time, instead of teaching only the political activism of African Americans during the civil rights movement of the 1960s.
- Focus on concepts and themes (i.e., identity, struggle, marginality, resistance, etc.) and how they are manifested over time within and among ethnic groups, as the center of multicultural education teaching and learning instead of studying first one ethnic group and then another.
- Provide multiple ways of learning and types of knowledge for all topics, issues, and events taught. These should allow for students' intellectual, affective, active, and reflective engagement, individually and collectively.
- Include techniques for ethnically diverse students to acquire the process skills and the social and cultural capital needed for understanding the substantive content to be taught. These might include how to identify cultural cues embedded in written texts, understanding the technical language of different disciplines, how to shift modes of behavior from one cultural system to another to improve academic performance, and how to take standardized tests.

Although multicultural curriculum has many common conceptual features and frameworks, they do not translate into a single universal model in practice. Too many situational factors impinge upon its actualization for this to be possible. The more important need is for educators to make thoughtful, deliberate, and informed decisions about teaching ethnic and cultural diversity with

due consideration given to localized and contextual factors and the scholarly funds of knowledge on multicultural education that already exists and is continuing to emerge.

## MULTICULTURAL CURRICULUM THEORY

---

Multicultural curriculum theory is the broad term for strands within curriculum studies that critically examine the sociopolitical, historical, economic, and cultural contexts of education with a focus on race, ethnicity, class, and gender as well as issues

of equity, social justice, and power. It evolved separately from, but connected to, multicultural education theory as theorists became concerned with inequality in schools and classrooms particularly as related to the achievement of historically disadvantaged students and the development of a democratic society. As a component of general curriculum theory, its major contribution to the field has been to highlight education issues related to marginalized students, to develop a language and terms to articulate these issues and to bring forward alternate ways to address these issues in order to create equitable environments for all students.

Multicultural curriculum theory was first brought to the center of curriculum studies discourse in the 1970s and 1980s by reconceptualist movement theorists who contested notions of curriculum as neutral and drew attention to previously neglected areas of inquiry, ones that centered on the raced, classed, and gendered nature of curriculum, teaching, and learning. It grew in prominence in the 1980s and 1990s as an interdisciplinary method to study curriculum in context, policy, and practice in terms of racial, ethnic, linguistic, religious, and other minority and marginalized students' education and experiences in schools and societies. It also developed as a system to explore the social construction of minority identity and disparate power relations in schools and societies. During this period, it evolved as a means to express a humanistic, social justice, and emancipatory orientation to curriculum and education. The late 1990s and early 2000s marked the beginning of a major development in multicultural curriculum theory that reflected the inclusion of the dynamics of globalization and international perspectives on issues.

Although there are variations in topics and perspectives that are identified with distinct strands of multicultural curriculum theory, there are also overarching principles and goals that provide a foundation for all multicultural curriculum theory. These principles include addressing fundamental issues of inequality in societies, institutions, and education with goals of prejudice reduction, elimination of bias and stereotyping, and empowerment of oppressed individuals and groups; recognition

of the contingent and constructed nature of knowledge and an ensuing critique of mainstream pedagogical and other practices; and development of policies, practices, pedagogy, curriculum, and evaluation procedures that are inclusive of diverse students' experiences and learning styles. Goals of creating an equitable education system for diverse students and a socially just society through transformation of individual attitudes and beliefs with concurrent reform of institutions also unify multicultural curriculum theory.

While adhering to core principles and overall goals, within multicultural curriculum theory there are multiplicities of substrands that represent different philosophical orientations to and disciplinary perspectives on the study of multicultural phenomena, have different historical roots, utilize different methods and starting points for inquiry, and have different, though related, foci of interest. These differences have led to intense debates and a rich, nuanced discourse in the field; one prominent focus has been the relevance of theory to practical issues in schools and classrooms.

Key substrands within multicultural curriculum theory can be broadly grouped under humanistic, critical, and emancipatory approaches. Humanistic approaches include the personal such as autobiographical, narrative, and existential studies that focus on an examination of issues at the microlevel in order to effect change at the macrolevel. Starting points of self, self in relation to others, and goals of personal transformation characterize these approaches. Much of the work in these approaches has focused on studies of culturally and linguistically diverse classrooms and schools, cross-cultural educational experiences, and preparation of teachers to work with diverse students. Critical approaches include critical pedagogy and Marxist orientations that focus on addressing issues at the social, political, and institutional level to effect change at the macrolevel to impact the microlevel. These approaches begin with institutions, policies, and structures as starting points with goals of reconstruction of educational and social life. Work within critical approaches include studies of race and racism, antibias and antiracist education, White privilege, inequitable allocation of resources in schools and society, and examinations of the

political context of curriculum. Emancipatory approaches use aspects of humanistic and critical approaches. They focus on complex questions of human potential, solidarity across difference, community, and social responsibility. The goal of these approaches is to raise consciousness and to elucidate possibilities for human life.

Humanistic, critical, and emancipatory strands overlap and compliment each other; together they constitute a robust body of scholarship in multicultural curriculum theory. Scholars are often associated with distinct strands; however, many contemporary scholars, such as those who study Whiteness, use a combination of approaches to address concerns. Various strands also have different content of inquiry. Foci of interest include specific racial, ethnic, or linguistic groups, within or across group differences, place specific orientations, and accommodation of curriculum to the needs of linguistic and cultural minorities. Contemporary multicultural curriculum theory discourse simultaneously engages these contents of inquiry with possibilities for a socially just education system and society.

## MULTI-VOCAL RESEARCH

---

Multi-vocal research often embodies the perspectives of diverse sets of authors such as academics, journalists, policy makers, classroom teachers, and parents. This method of writing aims to democratize research in curriculum studies by incorporating multiple perspectives rather than placing in relief the perspectives of a privileged group or dominant epistemic traditions. The term *multi-vocal* literally means many voices. In the context of curriculum studies, it is used to describe a form of research that represents multiple perspectives. First-person point of view is commonly combined with third-person omniscient narrative to represent a range of positions (often contradictory) on a single issue, phenomenon, or theme. The reading path of multi-vocal research is not arranged conventionally, but is often recursive, makes use of montage, performance, sidebars, white space, visual images, sound-tracks, and found objects. Experiments with multi-vocal research range from book reviews to theoretical arguments, conference presentations, online reports, and ethnographies.

The turn to multi-vocal research in curriculum studies can be traced to poststructuralist principles as well as to two key academic figures: anthropologist Victor Turner (1920–1983) and literary scholar Mikhail Bakhtin (1895–1975). Turner's study of the multiple meanings assigned to a symbol during ritual practices emphasized the multi-vocalic nature of symbols. A single symbol could have more than one referent and, in fact, often does. Turner found that symbols worked during ritual practices to bring together seemingly disparate meanings or themes simultaneously and can only be understood in context and according to the meanings that a community endows it with. Drawing on Sigmund Freud's *The Interpretation of Dreams*, Turner developed a practice and theory for interpreting symbols that explored the manifest (obvious), latent (partly

aware of), and hidden (unaware of) meaning embodied in symbols. The principle of the multi-vocality of symbols resonates to the intentions that often accompany multi-vocal research, especially the intent to portray the insights and understandings that challenge dominant values, beliefs, and policies.

Bakhtin, a Russian philosopher, literary critic and semiotician, emphasized the significant role that social context plays in generating meaning. His scholarship offers a substantive and elaborate conceptual critique of the limits of binary structures and the social, ethical, and aesthetic relevance of creating texts that create a dynamic interplay among many conflicting radiants of meaning. Rather than relying on the principles of a binary system such as openness-closeness, moral-corrupt, sickness-wellness, intelligence-ignorance, Bakhtin emphasizes the importance of creating more complex, multilayered meanings that capture nuance, contradictions, and sustain engagements with indeterminate meanings, for in the context of multi-vocal research, understanding is recognized as inherently incomplete. Bakhtin's suspicion of totalitarian, single-voice, synthetic, monologic forms of representations resonate as well to the ethics that accompany much of the esteemed multi-vocal research in curriculum theory. The central idea is that no one voice should subsume another and that the dynamic interplay of opposing forces be represented in order to further a more just society. Thus, multi-vocal research is rooted in a desire to represent voices that have historically remained beyond the pale in the annals of educational research. Multi-vocal research often seeks to represent those who are marginalized, perceived as untrustworthy, or exceed normative categories for wellness, intelligence, and integrity.

Although multi-vocal research has become prominent in curriculum studies, it has also met with serious critique. Concerns have been expressed that academic rigor is compromised, in part because the protocols traditionally used to determine if a study is reliable and valid are often not recognized as relevant when evaluating multi-vocal scholarship. Questions have surfaced about the review processes that multi-vocal research should undergo for publication, the ethics of involving participants in writing themselves into

multi-vocal reports-ethnographies and the extent to which participants such as students, patients, or teachers are coauthors of such texts written by academics and hence, responsible for the findings of the research projects.

## MYTHOPOETICS

---

Mythopoetics is the study of myths and their dysfunctional aspects found in the field of curriculum studies. The researcher-mythopoeist reports findings in poetic form. A myth in this context is an answer to an unanswerable question that has become a part of what is accepted as true. One such myth is that spirit is religious and hence unacceptable as part of the curriculum in the public schools because it violates the separation of church and state. When spirit is thought of as the dynamic principle, which is the life-force of all, it is not religious. In fact, it is a critical aspect of curriculum. Hence, to exclude the spirit in curriculum studies is dysfunctional. The methodology for studying myths and their dysfunctional aspects is demythologizing. The process of demythologizing has four major dimensions: (1) the substantive, (2) the syntactical, (3) the philosophic, and (4) the formal.

The substantive dimension is the study of the history and substance of myths by which education functions. Research in this field focuses on dysfunctional aspects of myths. The goal of such studies is understanding myths and determining what causes them to be dysfunctional. Another

example of myths and their dysfunctional aspects that mythopoeists have demythologized is that when scores in reading, math, and science go down, the best way to correct the decline is to do away with art, music, and physical education. Scientifically and practically this solution is not valid; hence, it is a dysfunctional aspect of the myth. The most poignant aspect of the substantive dimension in mythopoetic curriculum theory is the study of what Carl Jung called the spirit as a dynamic principle of the life-force in us all.

The syntactical dimension of demythologizing is the inquiry process. Mythopoeists take a multiple paradigmatic approach to assist in the inquiry process. This approach uses a series of stream metaphors to explicate the paradigms. Each phase of the stream metaphor addresses the role of the researcher, methods of inquiry, research subjects, objects and research goals. The paradigm that includes the objective, quantitative and documentary is called rational-theoretical; the researcher is on the edge of the stream being the objective observer/experimenter.

The research goals of the mythopoeist in this paradigm are generalizations, predictions and causal probabilities. The paradigm called mythological-practical has the researcher in a boat in the stream and acting as participant observer. The research goals here are naturalistic generalizations, action, and theories. In the evolutionary-transformational paradigm the researcher becomes the stream and studies self and interactions with others. The goals in this paradigm are change, healing, and transformations. In the critical-normative paradigm the researcher having experienced the other paradigms becomes critic and revisionist-activist. Participants in the feminist movement think and act primarily in this paradigm in which awareness, emancipation and demystification are the research goals. The mythopoeist is most often the bricoleur working in each-all of these paradigms and selecting appropriate research methods for the tasks at hand.

When thinking-acting in the philosophic dimension the researcher has multiple world views. The one that mythopoeists use most is phenomenology where primary experiences are basic reality. Heuristic inquiry, autoethnography, autobiography, and hermeneutics are commonly used methods (epistemologies) of inquiry to gain

understandings and affect-effect transformation-change and healing.

While demythologizing, the mythopoet may use poetry, stories, narrative, music, dance, sculpture, paintings, movies, photographs, rituals, signs, metaphors, architectural designs, dance, autobiography, letters, and portraiture to represent her or his research findings, insights, breakthroughs, and transformations as forms of presentation.

## NARRATIVE RESEARCH

---

Narrative research in curriculum studies is a relatively new social science methodology and grew out of F. Michael Connelly and D. Jean Clandinin's curriculum studies work on teacher knowledge. They called the method *narrative inquiry*. The terms *narrative research* and *narrative inquiry* are synonyms. Different Individuals outside of curriculum studies may use and interpret the terms differently. *Narrative inquiry* is commonly used in curriculum studies and is used in this entry.

Narrative inquiry is an experiential methodology for studying curricular experience. The key phrase is *experiencing experience*. Narrative inquiry is a comprehensive research methodology referring both to a method of inquiry and to the phenomena studied. In narrative inquiry, that is, in *experiencing* (method) the *experience* (phenomena), narrative is the phenomena of curriculum inquiry because teachers, students, and others experience curriculum narratively. Narrative is the method of inquiry because the inquiry process is an experiential and collaborative process for the researcher. Narrative inquiry is the *experiential study of curriculum experience*.

The significance of narrative inquiry for curriculum studies is that researchers participate in the curriculum experience under study. Narrative inquiry in curriculum studies is a holistic experiential study of all aspects of curriculum (learner, teacher, subject matter, and milieu), both in and out of classrooms and schools.

## Narrative Inquiry and the Concept of Experience

### *The Black Box of Experience*

*Experience* is the key term in narrative inquiry. *Experiencing experience* means that curriculum experience is studied experientially. Much curriculum research treats experience as a black box, taken-for-granted, but not studied. In input-output studies, for example, a new curriculum may be introduced (input) and its effects studied (output) by evaluating student achievement after using the new curriculum, by studying teacher attitudes toward the new curriculum after using it, or by studying parental responses to having their children exposed to the new curriculum. The *experience* connecting these results to the new curriculum is the black box between input and output. Student achievement, teacher attitude, and parental response data say nothing about children's, teachers' and parents' actual experience of the new curriculum.

Narrative inquiry opens the black box to inquiry into curricular experience. In the example introduction of a new curriculum just described, researchers would participate in teaching the new curriculum. They would explore such things as how students interacted with the curriculum and with one another inside the classroom, and with parents and others outside of the classroom. They would explore student and teacher prior experience relative to the curriculum and examine the goals that students and teachers thought the curriculum served. The researchers might visit parents

in their homes and places of work, and they might attend parent-teacher interviews. In this way, what happens between input and output is experienced and studied.

### *The Meaning of Experience*

Connelly and Clandinin observe that arguments for using narrative inquiry are inspired by a view of human experience in which humans lead storied lives. People shape their daily lives by stories and they interpret their past in terms of these stories. Story is a portal through which a person enters curricular situations and by which his or her experience of curriculum is interpreted and made meaningful.

Seen in context, and understood experientially, stories are complex. They grow out of past experience, and they shape the way future events are experienced and interpreted. Stories occur in a social context and, although a person's story is personal with particular emotional, aesthetic, and ethical qualities as experienced by that person, stories also express and reveal the environment in which the story is experienced and told. To reflect these features of story and experience in narrative inquiry, Connelly and Clandinin developed a metaphor of a three-dimensional narrative inquiry space. They drew on John Dewey's criteria of *interaction* and *continuity* as well as his notion of *situation* to study people's lived experience. The three dimensions of a narrative inquiry space are (1) personal and social (interaction); (2) past, present, and future (continuity); and (3) place.

### *Experience and the Life Space*

The three-dimensional narrative inquiry space framework guides a researcher's data collection in curriculum life spaces. Whereas much curriculum research is aimed at describing things as they are, narrative inquiry takes things as they are and asks how they came to be this way. Inquiry questions about what is observed are asked along each dimension: past, present, and future questions; personal and cultural/social questions; and questions about place. This idea of experience means that curriculum researchers are in a life space that is holistic, dynamic, living, and unfolding, rather than fixed, static, and something to be fixed by

description. For the new curriculum example, the life space includes the classroom where the curriculum is taught, but is not limited to it. The space also includes out-of-classroom settings in the school, home, and community. Participants include teachers, students, researchers, and others who play a role in how the curriculum is experienced in the life space. Inquiry is pursued along each of the life space dimensions for various participants and for various settings.

### *Story and Curriculum Experience*

The stories people tell in the life space give meaning and significance to their curricular experience. For instance, if the new curriculum is in art, some children may do poorly saying they are not artistic and cannot draw, while other children may do well saying they love art and are good at it. A teacher might believe that modern society depends on science and technology and tell a curricular story of needing to get through the art curriculum quickly to pursue more important things. Another teacher may believe in the social value of the arts and may enthusiastically teach the curriculum, bring in extra resources, and encourage reluctant students. The *experience* of the new curriculum will be different for students with different stories of themselves relative to the art subject matter of the new curriculum, and the experience will be different when the curriculum is taught by teachers with different stories of the value of the art curriculum. These differences provide an explanation for different results in input-output studies.

### **What Does a Narrative Inquirer Do in the Life Space?**

A narrative inquirer's task is to *experience the experience* being studied. Four guidelines for a narrative inquirer's actions are establishing a collaborative sense of purpose with participants; participating in whatever is going on in the life space; recognizing that the researcher has a different relationship to the life space than do other participants and that it is her or his responsibility to craft the explanatory narratives emerging from the research; and relinquishing ultimate responsibility for what is happening in the life space. This last guideline may create tension for narrative inquirers who

invest themselves in a curriculum life space. When researchers enter a curriculum life space it is ongoing, and when the inquiry concludes the life space continues. Narrative inquirers are temporary members of curriculum life spaces under study.

The degree to which a narrative inquiry researcher participates in a life space influences what a narrative inquirer does. In some curriculum studies, whether by preference on behalf of the narrative inquirer or by circumstances imposed by the life space, the researcher's participatory access to the life space is restricted. Returning to the new curriculum, a narrative researcher may enter the life space after the curriculum has been taught and may inquire *retrospectively* by studying the life space vicariously through *tellings* in interviews, conversations, and other interactive social arrangements with participants. Full participation in the life space leads to a different way of being, and doing things, in the life space than does inquiry conducted retrospectively. The difference leads to two general types of narrative inquiry studies: *telling* studies and *doing* studies.

### *Ethics*

Researchers need to be aware of institutional policies on ethics. In Canada, for example, the ethics for all social science research is governed by the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans. The Tri-Council is a joint body of the Canadian Institutes of Health Research, the National Sciences and Engineering Research Council, and the Social Sciences and Humanities Research Council. A university researcher conducting narrative inquiry into curriculum in a school or school board normally completes two ethical protocol reviews, one at his or her home university where Tri-Council Policies are built in to the process, and one at the school board which normally has school board specific policies.

Narrative inquirers need to consider ethical matters from beginning to end: during opening negotiations with potential participants, in relationships during inquiry, and in the writing up of results. Janice Huber and D. Jean Clandinin show how narrative inquiry can influence the experience of life space of participants. Ethical considerations are guided by relationships established during

inquiry in the life space. Narrative inquirers need to consult their own consciences as a guide for their ethical conduct during narrative inquiry.

### Collecting/Writing Field Texts

The fact that people make meaning of their lives through story sometimes leads to the mistaken view that narrative inquiry field work is the collection of stories. Stories are collected during field work. But stories are a small part of the range of field records collected. Narrative inquirers use the term *field texts* rather than *data* when discussing evidence recorded during research. The reason *field texts* is preferred to *data* is that the word *field* implies a place where the record is collected whereas *data* carries an abstract sense independent of place. The term *texts* conveys a complex quality, and *data* has a unitary quality. In addition, *data* tends to carry a fixed idea of the record, for example, a record of achievement on a mathematics test, whereas *field texts* is open to whatever might bear on the life space.

There are potential conceptual difficulties with the use of the term *field text*. Narrative inquiry is an experiential, field-based, form of research, but the idea of *text* suggests discourse *about* life situations. Ian Westbury wrote that there was a turn to text in curriculum studies in critical, theoretical, and postmodern research based on texts rather than on curriculum experience. To the extent that the term *field text* suggests this abstract turn in curriculum inquiry, the term misrepresents narrative inquiry.

Narrative inquiry uses the following field texts as data sources: field notes, personal stories, family stories, photographs, autobiography, journals, letters, conversations, interviews, participant observations, and any life experience record and artifact bearing on the inquiry.

### History of Narrative Inquiry in Curriculum

Connelly and Clandinin were the first to name and describe narrative inquiry as a social science research methodology in curriculum studies. They wrote about teachers as curriculum makers: their lived experience and personal practical knowledge. They, their students, and others have studied curriculum reform policy, teacher knowledge, student

experience, multiculturalism, administration, and cross-cultural work in curriculum. In recent curriculum research, narrative inquiry is used to study the curriculum of ethnically, culturally, and linguistically diverse societies. The work has expanded within curriculum studies and is used in many social science fields.

The expansion of narrative inquiry led Connelly and Clandinin to say that narrative inquiry is positioned *in-between* abstract, formalized, inquiry, and concrete, empirical, factual inquiry. Clandinin and Jerry Rosiek expand the formal side to a set of philosophical assumptions at three formalistic inquiry borders with narrative inquiry—postpositivism, Marxism and critical theory, and poststructuralism. However, the reductionistic boundary is most important for curriculum researchers. For example, in the United States, where accountability and student achievement are powerful forces in the context of the No Child Left Behind Act, the experiential, holistic quality of narrative inquiry often runs counter to a reductionistic input-output focus in the school curriculum.

### An Example of Narrative Inquiry

Shijing Xu studied newcomer-Chinese family experience of curriculum in Canada. Though much was known about the achievement levels and career trajectories of Chinese newcomers, their curriculum experience was mostly an unknown black box. Xu *experienced the experience* by working intensively in one school and its community for 4 years. She participated daily with language teachers, regular teachers, settlement workers, parent center director, school administrators, parents, students, and community workers. She spent time in classrooms, homes, and parents' places of work. She joined in family and community social gatherings, and she participated in a wide variety of school curriculum and school–community cultural events. Following a lengthy trust-building process, she served as a cultural bridge between home, school, and community. Teachers and school administrators asked her to translate and to intercede with students and parents. Parents and children came to see her as an advocate able to understand their culturally and linguistically derived questions and sources of tension. Every day after returning from the field, she made computerized field notes and

filed-collected documents. Based on her experience and the field texts, she showed how intergenerational family narratives, traced back to Confucian times in China, interacted with Canadian cultural, educational, and curriculum narratives. She showed how newcomer-Chinese experience of the curriculum was understandable in terms of the intersection of intergenerational narrative threads as the two cultures interacted in the curriculum. This experiential understanding led to policy suggestions emphasizing reciprocal, cross-cultural, curriculum possibilities.

## NATIONAL ASSESSMENT OF EDUCATIONAL PROGRESS

---

Also known as “The Nation’s Report Card,” the National Assessment of Educational Progress (NAEP) originated in response to demands for indicators of the results of large government expenditures for curriculum development in the aftermath of *Sputnik* and the country’s fear that the Russians educational system was exceeding that of the United States. Billed as the gold standard of education assessments and the only nationally representative and continuing assessment of what U.S. students know and can do, it is currently administered periodically in mathematics, reading, science, writing, the arts, civics, economics, geography, and U.S. history. The instrument today, however, is different in both form and function from what was originally envisioned by its creators, most notably Ralph Tyler.

Varied interpretations of NAEP’s key purpose are suspected as the cause for its several incarnations since the first version in 1969. Disagreement on the matter of purpose was present even at NAEP’s inception, as can be noted by the stories of two key players, Tyler and Francis Keppel, the U.S. Commissioner of Education. Keppel was seeking precise data to support policies of the federal

government and turned for advice to Tyler, whose reputation as head of evaluation for the Eight Year Study and experience as director of the Center for Advanced Study in Behavioral Sciences at Stanford made him a logical choice. Tyler agreed in 1963 to chair the Exploratory Committee on Assessing the Progress of Education (ECAPE), to be underwritten by the Carnegie Corporation. He recognized the inadequacy of existing standardized tests for providing information about the educational attainments of large numbers of people of various ages over time. The task of providing the census-type portrait of U.S. educational achievement and the wealth of information it could provide for educators required an objectives-based model, akin to that of the Tyler Rationale.

The difference in Tyler and Keppel’s motivations is subtle, but powerful, and concern over the connection of educational assessment to public policy making was one of the first difficulties Tyler had to negotiate. Historically, curriculum scholars have had qualms about standardized testing. As early as the 1927 *Yearbook of the National Society for the Study of Education*, they noted it as one of the most effective forms of curriculum control, and they decried its tendency to emphasize memory of facts to the neglect of more dynamic instructional outcomes. Even some of ECAPE’s members expressed misgivings that NAEP might eventually drive a national curriculum. School administrators, stung by criticism after *Sputnik*, were especially concerned, fearing both the loss of local control and the use of assessment for comparison purposes.

Tyler labored to allay the fears of administrators and state superintendents. Citizen panels were formed to provide input on appropriate learning objectives for the targeted ages of 9, 13, 17, and “young adult.” The assessment was designed to consist of “exercises”—short-answer questions and performance tasks, as well as multiple-choice items. They would be read aloud for subjects other than reading, so that even poor readers could demonstrate what they knew. Because the goal was to provide the public with concrete, specific evidence of the skills and knowledge of respondents, reporting by overall test score would have no meaning. Instead, results would be reported for individual exercises, showing the estimated percentage of the population or subgroups that answered each

exercise correctly. ECAPE committed to reporting results by age and demographic group, but not by state, school, or individual.

Resistance waned when the Education Commission of the States took charge of the test in 1969. However, the first iteration of NAEP was not fully administered before social and political conditions began chipping away at its design. In addition to gradual changes over the years, a major redesign occurred when responsibility for it was transferred to the Educational Testing Service in 1984. Increasingly, NAEP was expected to provide information for policy making, information that often conflicted with its basic design. Contrary to Tyler's vision, it has now been reformulated for interstate comparison, and results are reported in terms of what students should know and be able to do at three levels of achievement: basic, proficient, and advanced.

NAEP is now governed by the National Assessment Governing Board, appointed by the secretary of education. The National Center for Education Statistics retains responsibility for NAEP operations and technical control.

## NATIONAL CURRICULUM

---

National curriculum is a public representation of what are considered the purposes of education at a national level, and it serves as a documented map of theories, common beliefs, and ideas about

schooling, teaching and learning, and knowledge—evidence in the development of teacher-proof curriculum. National curriculum is generally developed and mandated by a national jurisdiction to provide the same basic education to all students mainly in public schools across a country. National curricula commonly establish national standards for the performance of all students in the subjects they include. They mostly incorporate overarching legal statements that outline how teachers can modify, as necessary, curriculum programs of study to provide all schoolchildren with relevant information at main key stages.

Many developing countries and countries in transition to market economies have a highly centralized education and state-mandated national curriculum. The main argument of proponents of a national curriculum in these countries is that there is need to promote greater uniformity across education systems to help students required to transfer across regional boundaries. Another argument is based on the economic rationale that nationwide curriculum promotes financial effectiveness through the sharing of limited resources across systems, such as curriculum materials and curriculum development. Furthermore, the proponents argue that a national curriculum concerned with teaching all groups a common language, cultural heritage, and set of common values is a major instrument to develop a sense of national identity. For them, decentralization of curricula development will work against this aspiration.

Until the 1960s, the United States had decentralized but remarkably similar curriculum identities in many individual states, confining their curriculum development to visits by key officials organized to exchange information and ideas. At the beginning of 1970s, the centralized administration of each state began to ensure that there was uniformity of provision across the state boundaries to provide the same basic education to all children within the state. This rationale of establishing commonality of official curricula across state boundaries—so that students who move to another school district or even to another state are not disadvantaged—has been a recurring matter since the early 1970s. Furthermore, the ideal of U.S. common curriculum was charged with teaching future U.S. citizens a common language, a code of

conduct, shared values, and common ideals while providing the same experiences, the same curriculum, and the same opportunities to all students.

After the Education Reform Act 1988, England, Wales, and Northern Ireland developed their nationwide curriculum for primary and secondary state schools to ensure that state schools of all local education authorities have a common curriculum, which secures an entitlement to an equal education for all citizens. However, opponents note that the largely centralized production of these “official” national texts has resulted in a codified curriculum producing a new social order reflective of dominant groups.

During the 1990s and early 21st century, many developing countries began to initiate the process of decentralization of curriculum development and of localization of curricula in national and local specific contexts in view of ensuring greater responsiveness to local needs and realities. Today in many of these countries, there have been pressures from regionally based ethnic and language groups to develop their own curricula, teach in their own languages, and administer their own schools. In Spain, for example, initially the Basque and Catalan regions gained the right to manage their own educational systems and develop their culturally responsive curricula, followed later by other regions.

## NATIONAL SOCIETY FOR THE STUDY OF EDUCATION

---

The National Society for the Study of Education (NSSE) was an organization of scholars, professional educators, and policy makers. Among these members, the NSSE strove to create a vigorous, inclusive dialogue that addressed educational problems and focused on the relationships between pedagogical research, policy, and practice. To catalyze this dialogue, the NSSE hosted meetings, engaged in interorganizational conferences, and published a two-volume, annual yearbook.

Having originated from the National Herbart Society (1895–1901), christened for the revolutionary educational thinker, Johann Friedrich Herbart (1776–1841), the NSSE was founded in 1901 and published its first yearbook in 1902. Each yearbook was thematically centered on a particular educational issue that interested the general public and the NSSE’s members. For instance, the 1983 Individual Differences and the Common Curriculum issue contained articles about the multifaceted nature of individual differences and how curricular designers can accommodate student variability. Similarly, the 1988 Critical Issues in Curriculum edition contained articles about tracking, testing, textbooks, and other compelling educational dilemmas and practices. Initially, such topics were investigated and written about by an assembled committee, but later authors were solicited to individually contribute. The ultimate goal for the volumes was to provide a foundational perspective of the topic.

To provide this foundational but pluralistic perspective, the NSSE has featured such eminent and diverse authors and editors as John Dewey, E. L. Thorndike, Lawrence Kohlberg, Benjamin Bloom, and Jerome Bruner. Such efforts resulted in much praise for the yearbook from the academic and educational communities. Despite these efforts, the NSSE had been occasionally criticized for being too conservative, dismissing progressivism, and having an overly cabalistic and cloistered board of directors. But these problems were not as severe and consistent as NSSE’s low membership.

Membership dues were an important source of income, and ultimately the lack of members and other related factors rendered the NSSE financially

unfeasible. Thus, at the conclusion of 2008, the NSSE no longer functioned as a membership society. The NSSE's assets, including its yearbooks, became the property of the Teachers College Record (TCR), at Teachers College, Columbia University, in New York City. Under TCR's auspices, the yearbook has continued its publication, and the NSSE's archives have been digitized.

## NATION AT RISK, A

---

*A Nation at Risk* was issued by the National Commission on Excellence in Education, which found poor academic performance at every level of schooling. Signaling the development of new priorities for the federal government's approach to education reform, it was used by President Ronald Reagan's administration to frame the education debate in cold war terms and warned of a "rising tide of mediocrity." The report equated the state of education in the United States to an "act of war" and made direct comparisons between the economic competitiveness of the U.S. economy and other countries, particularly Japan, South Korea, and Germany. Additionally, the report cited a number of "indicators of risk" that included declining SAT scores; low student scores in literacy, science, and math; and poor showings on international comparisons of student achievement.

The commission placed the blame for these academic shortcomings on incompetent teachers and lazy students and offered the following recommendations, some of which have had moderate success, as noted below:

- Calling for strengthened graduation requirements, the report stressed a core curriculum and recommended that all students take a minimum of 4 years of English, 3 years of mathematics, 3 years of science, 3 years of social studies, and one-half year of computer science. In 2005, the U.S. Education Department found that 36% of high school graduates had completed such a curriculum, improved from 26% in 1990.
- Schools and colleges should adopt more rigorous and measurable standards for academic performance. Although some state standards aimed high, critics report that most states have selected tests that do not measure what is actually taught. Critics also contend that an unintended by-product of this recommendation is a teaching-to-the-test mentality that has resulted in a curricular reductionism that gives little attention to curriculum content not assessed by accountability tests. Many districts now impose test-preparation drills on their teachers and students rather than teaching all academic subjects.
- The amount of time students spend engaged in learning should be significantly increased to 7-hour days with a 200- to 220-day year. Only a few charter schools have extended days and the school year, but most public school systems have not.
- The teaching profession should be strengthened through higher standards for preparation and professional growth, and salaries should be professionally competitive. Although a recommendation in this 1983 report, this became mandated through the No Child Left Behind Law of 2001, when every teacher had to be "highly qualified."
- Citizens should hold educators and elected officials responsible for leadership and fiscal support to drive reform. Although many governors have called themselves "education governors," few have chosen to reform public schools. Rather, they have chosen to support school vouchers and choice options.

Truly a watershed moment in educational policy, the report served as a demarcation for the start of the curriculum standards movement. It also inaugurated a series of attacks on public schools and ultimately united politicians and businessmen into claiming control over the country's public education system.

In 1989, the nation's governors met in Charlottesville, Virginia, with President George H. W. Bush. The general consensus at the education summit was that despite grave concerns announced in *A Nation at Risk*, little had been accomplished in terms of student achievement. In a final press release, conference participants stressed the need for creating a "system of accountability" and called for more systematic reporting of school, district, and state performance; increased parental choice; school-based management; and alternative certification for teachers. Thus, Bush's education summit represents a pivotal turning point because it links the politically driven, but essentially unmandated, *A Nation at Risk* of 1983 to the legal enactment of national education policy that culminated in President George W. Bush's No Child Left Behind Act.

on educational programs and practices to be funded by the federal government. The No Child Left Behind Act (NCLB), enacted in 2002, specifically states in more than 100 of 200 references on educational research that such research be "scientifically based." In NCLB, scientifically based research is defined as that work involving objective and rigorous procedures resulting in valid and reliable data applicable to educational activities and programs. The meaning of the term *neocolonial* stems from political theory and was first used by the Ghanaian scholar, Kwame Nkrumah, in 1965, to describe the continuing imperialism exerted by the former colonial powers on the newly sovereign African states primarily through economic and monetary measures. More recent analyses of neocolonialism emphasize the importance of cultural, social, and political factors in addition to the original, narrow economic focus. In its imprimatur of scientifically based research in education, the federal government indirectly devalued all other forms of educational research, resulting in the use of the term *neocolonial research* to describe a form of imperialism exerted through the funding and through the culture of federally sanctioned educational practices.

Subsequent to the passage of NCLB, the National Academy of Sciences published a guide on the application of scientific research (SR) to education. The academy established six principles for acceptable scientific research:

1. SR poses significant questions that can be investigated empirically.
2. SR links research to relevant theory.
3. SR uses methods that permit direct investigation of the question.
4. SR provides a coherent and explicit chain of reasoning.
5. SR replicates and generalizes across studies.
6. SR discloses research to encourage professional scrutiny and critique.

To manage the funding and dissemination of SR in education, the federal Institute of Education Sciences (IES) was established and replaced the Office of Educational Research and Improvement. The use of randomized experiments became the

---

## NEOCOLONIAL RESEARCH

---

*Neocolonial research* is a term applied to the form of education research designated by the U.S. federal government as the dominant form of research

gold standard of research designs and constituted those research projects most likely to be funded and endorsed by the federal government.

Alternative forms of education research—such as research based on qualitative methods and grounded in postmodernism, poststructuralism, cultural, critical, critical race, and feminist theoretical approaches in which knowledge is construed as complex, multifaceted, contextual, and thereby, problematic—were deemed questionable from a scientific design perspective. As a result, the IES has funded very few studies based on these alternative forms of research. The singular focus of the federal government on SR in education reversed several decades of advances for alternative research approaches. Beginning in the 1970s, education research methods shifted to the qualitative paradigm as a result of the difficulties of the then-dominant paradigm of quantitative and SR in measuring educational significance and in determining causal models because of the preponderance of interaction effects within the context of schooling.

In addition to directing the form of the production and dissemination of research, the federal government also required funded programs to show evidence of applying the findings of SR to their practice, thus adding curriculum to the federally defined domain of acceptable research practices. One curricular area most affected by these requirements is reading, specifically the federally funded Reading First programs for low-income students. Based on the findings of the National Reading Panel (NRP), Reading First programs require schools that receive grants to focus reading instruction on phonemic awareness, phonics, developing fluency, vocabulary, and text comprehension. To receive funding, states must also demonstrate to the federal government how they will assist school districts in ensuring that local districts that receive federal and state funding have engaged in professional development for teachers based on scientifically based evidence, an additional expansion of the use of neocolonial research. The political process, funding, and results of SR in the Reading First programs have come under increasing scrutiny regarding the reliability of SR across samples and, therefore, the replication of Reading First programs. Policy decision making has also been affected by contradictory SR findings

in the areas such as the charter school research and the federally supported voucher program in the Washington, D.C. schools, leading educational experts to conclude that that no single research study can provide the definitive answer to application of research to curriculum or policy because of the limitations of data and the complexity of schooling and community.

## NEO-MARXIST RESEARCH

---

Neo-Marxist curriculum studies is a field of inquiry concerned with the complex connections between broad, economic structures and inequalities and the everyday production of school knowledge. Often called the “new sociology of education,” neo-Marxist research in curriculum studies explores how class inequality is “naturalized” through the school curricula. That is to say, it is concerned with how official school knowledge or curricula is complicit in the reproduction of class inequality. The earliest, most important work in this field emerged from the United Kingdom (e.g., the work of M. F. D. Young, Geoff Whitty, and Basil Bernstein)

and France (e.g., Pierre Bourdieu and Jean-Claude Passeron) during the mid-1970s before becoming more pronounced in the United States during the 1980s (e.g., Michael Apple and Jean Anyon). In many respects, neo-Marxist curriculum studies was a response both to dominant structural-functionalist models of schooling (e.g., Émile Durkheim and Talcott Parsons) as well as more orthodox Marxist ones (e.g., Samuel Bowles and Herbert Gintis). The current rising tide of neoliberalism and its attendant, global economic stratifications and inequalities has brought renewed attention to this field of inquiry.

### Structural-Functionalist and Orthodox Marxist Models of Schooling

Structural-functionalist models of schooling were dominant throughout most of the 20th century. Such models of schooling assumed society a well-functioning, integrated whole. The primary purpose of schooling was to maximize social efficiency by sorting young people according to their ability and potential. The goal was to maximize “human capital”—that is, to use human resources most efficiently to maximize the broad social capacities of the nation-state. The cold war brought these concerns to the forefront during the late 1950s, particularly in the United States. With the USSR’s launch of *Sputnik* in 1957, many were concerned that the United States was falling behind in the sciences, leading to a renewed interest in public education.

These structural-functional notions of education were questioned during the 1970s. In their famous book, *Schooling in Capitalist America*, Bowles and Gintis argued that schools work to reproduce deeply classed and inherently unfair social relations. More than anything, schools work to “sort” young people into a stratified and deeply hierarchical capitalist system, one that exploits the labor of the working class to the benefit of elites. As Bowles and Gintis famously argued, school reform was largely a hopeless endeavor in a capitalist system. Family income was a far greater predictor of future social class than was IQ or school achievement. As with structural-functional work, schools were treated here as “black boxes.” The particularity of school curricula and everyday teaching and

learning practices were not considered important or relevant. The macrolevel perspective exhausted all possible discussions and questions.

### Key Scholars

Work in the “new sociology of education” opened this so-called black box, looking at all the ways in which curricula itself worked to effect social and economic reproduction. Much of this work was drawn together in the highly influential volume, *Knowledge and Control: New Directions for the Sociology of Education*, edited by Young. This collection included contributions by (among others), Young, Bernstein, and Bourdieu—all of whom would be critical for the field.

Like many neo-Marxist curriculum scholars, Young was interested in the connections between social stratification and knowledge stratification. In particular, he was interested in the ways schools marginalized working-class youth by producing arbitrary and unfair distinctions between “high” and “low” status knowledge. The former is so-called pure, rather than applied knowledge. Such knowledge operates at the level of broad generalities, not specificities. This distinction helps explain why vocational education is typically marginalized in school settings. Often attractive to working-class youth, this kind of education is often marked as low status. For Young, these distinctions between high and low status knowledge help explain why schools do not serve the needs and interests of working-class youth.

In arguing for this, Young underscores a point that would be critical to the new sociologists of education—that knowledge itself was a social construction. This insight creates a critical space to think about the curricula as a politically contested construct. Curricular knowledge is not simply “given” but a function of power. This raised a series of questions, including these: Who controls the curricular knowledge? And whose interest does it serve? For Young and others, this is not only a question of curricula content. It is a question of how knowledge itself was organized. More specifically, Young was interested in the question of how knowledge becomes specialized and how this specialized knowledge falls under the purview of the elite. Indeed, the separation of knowledge into

discrete disciplines was itself a function of power. All of this worked to create specific kinds of knowledge stratifications that helped maintain broader kinds of social stratifications. For Young and others, the pressing question was one of social class.

Bernstein was another key figure in neo-Marxist curriculum studies. Bernstein's earliest work looked at class differences and language use. Bernstein was interested in the linkages between symbolic structures, broader structures, and everyday experience. More specifically, he was interested in how social orders reproduce themselves through microlevel speaking practices. Yet, he was not only interested in describing these practices. He was interested in developing a way to understand how language use could critically intervene in the reproduction of unfair social structures. Throughout his career, he was interested in finding ways to prevent the marginalization or "wastage" of working-class talents.

Bernstein soon took up questions of education and the ways language practices prepare youth for school success in distinct ways. In early articles such as "On the Classification and Framing of Educational Knowledge," first printed in *Knowledge and Control*, Bernstein explored the ways curricular knowledge is "framed" in school settings. Bernstein was less interested in the particular content in educational curricula than in the formal dimensions of how knowledge is dispensed and controlled. Bernstein highlighted the idea that different kinds of knowledge (e.g., different school subjects) can be rigidly separated from each other or can be more loosely interpenetrated. He called the former "collection code" type of curricula and the latter an "integrated code" type of curricula. As he argues, classification is about the relationship between curricular contents—not their content per se. This classification can be strong or weak. For Bernstein, the degree of "boundary maintenance" between different kinds of knowledge was a function of power. Bernstein was also interested in the ways teachers and students were able to "frame" curricular knowledge in pedagogical settings. Here, Bernstein was interested in whether students and teachers could freely rearticulate these boundaries or not. A key question becomes to what degree students can introduce their own everyday knowledge into school settings.

Bernstein was thus centrally concerned with questions of power and authority in school settings, with particular attention to how knowledge is organized and disseminated. Like Young, he was interested in the ways in which broader social hierarchies were connected with and instantiated in the organization of school knowledge. This work wrestled with the ways decisions about knowledge or curricula stratification could both support and disrupt broader social stratifications. The focus was primarily on questions of social class.

Another key scholar in neo-Marxist research in curriculum studies is the French sociologist Bourdieu. Beginning in the 1970s, including in the volume *Knowledge and Control*, Bourdieu raised a series of questions and issues that proved central to neo-Marxist curriculum studies. In 1977, he published, with Jean-Claude Passeron, the seminal *Reproduction in Education, Society, and Culture*. This volume brought together and crystallized many of his most central insights for the field. Like others in neo-Marxist curriculum studies, Bourdieu was centrally concerned with showing how school curricula served the interests of the elite, even as it appeared neutral and disinterested.

More than anyone, Bourdieu raised important questions about the nature of "elite" cultural activities and the process by which they become legitimated. As Bourdieu argued, so-called high art forms enter a certain intellectual field that is controlled by and serves the interests of the elite. This intellectual field—and its associated critics, teachers, other artists, and so forth—confers a particular kind of legitimacy on these forms. These elite art forms are often quite different from those privileged by the working classes. So, for example, classical music is privileged above interior design or cookery. The particular power of these distinctions is that they do appear as "elite." Their power is made to appear natural and immutable.

Schools play a particular role in this process. For Bourdieu (and Passeron), schools reward the cultural dispositions of the elite, translating them into different kinds of success and achievement. In particular, schools translate the "cultural capital" that elites typically grow up with into "economic capital." In turn, schools marginalize working-class youth—committing a kind of "symbolic violence" on them. For Bourdieu, this violence is arbitrary, as are these cultural distinctions. They

work only to reproduce the power of elites—here, through school knowledge.

Anyon and Apple are perhaps the most prominent and important neo-Marxist researchers in curriculum studies in the United States. Beginning in the late 1970s, Apple and Anyon brought these concerns to the United States. Apple's important first book, *Ideology and Curriculum*, looked at the ways in which school knowledge was (borrowing from Raymond Williams) the result of a "selective tradition" that worked to maintain capitalist hegemony and produce capitalist ideologies. Drawing on Italian theorist Antonio Gramsci, Apple saw school curricula as a site of struggle—one of resistance and incorporation—though largely around issues of social class. Like the neo-Marxist scholars noted earlier, Apple was interested in showing the power of the curricula to appear neutral and disinterested. The technocratic and seemingly "scientific" approach to curricular knowledge and human capital belies their service to the elites.

Anyon's work started a more explicitly empirical approach to the question of the production and dissemination of school knowledge—though one firmly rooted in neo-Marxist theory. In particular, Anyon looked at the ways different types of schooling prepared youth for different kinds of relationships to work. Her great achievement here, however, was to open the so-called black box and explore how this all worked. She looked at the attitudes of school personnel to knowledge, the role of curriculum-in-use, as well as young people's perceptions of knowledge. All had different implications for one's class position. For example, in various pieces, Anyon shows how working-class youth and teachers had a rule and skill-oriented relationship to school knowledge. One had to learn the most rudimentary responses to what were perceived as arbitrary questions and problems—so-called drill and skill. Creativity was not encouraged. These students were being prepared to follow the orders of their bosses in menial labor type jobs. Young people here do not have an active relationship to knowledge. As one moves across the class spectrum—from workingclass, to middleclass, to affluent professional, to elite schools—one sees young people having more and more control over school knowledge and the curricula. In elite schools, the "right answer" is not stressed. The nature of problem solving is. That is to say, these

youth are being prepared to set the rules for others—to have absolute control over knowledge. All of this implies different relationships to the curricula across numerous disciplines.

### New Directions

Many of this generation of neo-Marxist critics have expanded their work to address other kinds of inequalities. For example, Cameron McCarthy's well-known work has looked at the nonsynchronous relationship between class, race, and gender, assuming all need to be looked at in context-specific ways. McCarthy challenges the often reductive or additive forms of multiculturalism that became most pronounced in the United States during the 1980s. McCarthy's work retained the traditional neo-Marxist focus on the materiality everyday life. That is to say, he stressed the ways in which the relationship between these forms of difference are complex and contradictory and need to be explored "on the ground." While remaining tied to the traditional neo-Marxist focus on economic inequality, McCarthy examines how gender and race can complicate seemingly deterministic or isomorphic relationships between and among them. Like many neo-Marxist curriculum scholars, McCarthy focused largely on how these dynamics were embedded in particular texts—specifically, works of art and literature.

Apple has remained perhaps the most prolific of neo-Marxist curriculum scholars in the United States. However, his work has moved in several new and interesting directions. Most specifically, his recent work has focused on the ways in which the "new Right" has drawn together four distinct power-blocks in forming a new kind of alliance. These are the new, managerial middle class; evangelical Christians; cultural conservatives; and adherents to neoliberal economic policies. New economic regimes—in particular, those associated with deregulation and neoliberal reform—have had to justify themselves with these new kinds of connections and associations. As Apple writes in *Educating the "Right" Way*, the rise of No Child Left Behind legislation in the early 2000s worked in tandem with neoliberal economic logics. More than anyone, Apple has stayed attuned to school knowledge and the evolving and increasingly exploitative logics of capitalism.

### Current Challenges

Neo-Marxist curriculum researchers today face several new challenges. As Young argued in a recent retrospective, the field has not developed a viable, alternative curricula to the one offered in school settings. The work has remained largely critical, often assuming the primacy of a de facto “common curricula” of the people. That is, if schools offered a largely “pure” and disconnected curricula that did not draw on the lives of the working classes, the solution would be an applied, vocational curricula that drew on the strengths of these groups. As Young argued, this was largely a fruitless effort to “flip the binary,” and did not answer more fundamental questions about which knowledge is most worth teaching.

Yet, the need for such work is pressing. In particular, global economic shifts over the past 20 years—marked by the rise of neoliberalism and neoliberal logics—have been profound, concentrating increasing amounts of wealth in the hands of very, very few. We are experiencing the largest income shift since 1929—a period often referred to as “the gilded age.” On one level, we see this evidenced in the well-documented move from an industrial to a postindustrial global economy where more and more young people will spend their lives working in service sector jobs that provide minimal income, few if any benefits, and little job security. Thus, further research regarding the role of school knowledge in reproducing and contesting these economic inequalities is needed.

## NEW LITERACY STUDIES

---

*New Literacy Studies* (NLS) refers to an approach to literacy and literacy education underpinned by three central ideas. First, literacy is seen as a communicative tool, with the emphasis firmly placed on its intersubjective aspects. In other words, the starting point for analysis is the way humans use texts to symbolize and transmit information to each other. Second, literacy develops to meet social needs, and this is true for literacy across societies and for individuals. When there is a task for which text use is necessary or desirable, then literacy strategies will develop. Third, and arising from these first two points, it may make more sense to talk about multiple “literacies” than a singular “literacy.” Taken together, these ideas have significant implications for the teaching of reading and writing and have been summarized as a “social practices” view of literacy. There are strong indications that the insights of the NLS have gone far beyond the immediate field of literacy teaching and learning.

The NLS developed during the “social turn” of the behavioral sciences in the 1980s and, in common with other developments of that era, features strong cultural relativism. There is resistance to the notion that any particular form of literacy is inherently more effective or valuable than any others. Any literacy practice is valuable to the extent that it is appropriate for its social context. The question of whether an approach to text is right or wrong

depends on its adherence to the set of norms within which it operates, and the notion of a standard orthography is undermined. To make this idea more concrete, consider a note on a fridge door that says “M. Sal etc.” This note exists within a specific social practice of literacy and communicates quite clearly to those engaged in that social practice; to them, the note means something like “Michael, remember to pick up salad vegetables and fruit when you pass the market on your way home from work.” This use of text is highly localized, but that does not make it less valuable, or less useful in literacy learning as a manifestation of textual production activities.

The NLS emerged in opposition to two central tenets of the approach to literacy dominant until the 1980s—what Brian Street referred to as the “autonomous” model of literacy. First, within the autonomous model, literacy was considered a set of individual cognitive skills, with reading typically broken down into lexical access and comprehension. More fluent readers were considered to have stronger skills, with implicit acceptance of the notion that there was a single continuum of skills involved in reading. Second, this model viewed literacy as an independent variable that brings about a series of effects such as cognitive development, economic development, and social progress. In this view, societies evolved from oral to literate stages, with the development of literacy having a profound effect on the society in supporting logical thought, extended territorial holdings, and the development of commerce.

NLS challenged this model and instead argued for what Street called an “ideological” model of literacy, which held that literacy practices are never just neutral skills, but are always embedded in social and cultural contexts. More than this, literacy practices are implicated in struggles over power, resources, and meanings. NLS scholars are skeptical of the idea that literacy changes people or societies, believing instead that literacy practices are essentially reactive, created and shaped within specific sets of human relationships.

The earlier views of literacy emphasized the cognitive processes and tended to regard comprehension of text as a rather mysterious process that depends on the undefined “schema” of the individual readers. In contrast, the NLS writings tend

to take the opposite stance, underemphasizing the mental work of textual interaction. So although the NLS is strong on antithesis to the psychological models and provides some invaluable insights, it has not yet offered a true synthesis of the individual and social processes of reading and writing.

The NLS has significant implications for the development of curricula and the practices of pedagogy. It suggests that there is the potential for a fruitful interaction of school and home literacy practices, with each supporting the other. For example, students can be encouraged to develop skills in both local and official literacies, rather than privileging school literacies. The NLS view also promotes the notion that learning should proceed from real life language use and social scenarios to more abstract ideas. Instructional time spent on understanding the social context of students’ text use will be highly beneficial to the learning process because it so profoundly affects what can be learned and how it will be learned. There is also a need to work from desired tasks to the skills that will support them. For instance, trying to learn grammar in the abstract will always be less effective than is learning it through the process of learning to communicate through writing. The way adults learn a new language illustrates these issues quite effectively. Learning a language through interactions with others who speak that language, in real life contexts where there is a need to speak that language, is more effective than is trying to memorize verb tenses in the abstract. The NLS would support the same process for interacting with texts and would see this as being more than a matter of learning styles. To these analysts, working with language, written or oral, is an irreducibly social experience.

Perhaps one of the most fundamental pedagogical implications of NLS is the reinforcement of diversity among learners. Students approach language, and indeed every subject, with experience and abilities already in place, and these are used as resources to construct meaning in new contexts. Rather than viewing the curriculum as a one-dimensional checklist of items to be covered, the idea of social practices encourages educators to blur the framing of learning, allowing the pace, sequence, and outcomes of learning to be more flexible.

The NLS conceptualization of literacy also holds implications for literacy research—namely, that one cannot research “literacy” as if it were something that exists independently from some social context. Instead, researchers must examine concrete practices of literacy—*literacy events* as Shirley Brice Heath calls them, or *literacy practices* in Street’s terms. *Literacy practices* refer to how reading and writing are used socially, and what meanings individuals make of their reading and writing practices. With the New Literacy models, there has been a shift in many literacy research projects toward more qualitative methods that focus on the social, cultural, and power contexts of literacy practices; research within the New Literacy Studies addresses social contexts and social change using methods such as ethnography and qualitative inquiry.

Educators and researchers in schools have explored the implication of the NLS quite extensively, looking at issues such as the way teachers protect and reinforce school-centered literacy practices and the way identities and social practices of literacy come together. In summary, the New Literacy Studies offers a range of interesting and insightful perspectives on the ways people interact with text in different settings. There is some way to go, however, in applying and developing these insights into a coherent educational approach. The attempts that have been made remain partial, strongly challenged by the difficulty of taking a highly relativistic theory and using it as a frame for defining the knowledge and practices to be valued in the classroom.

## NO CHILD LEFT BEHIND

---

The No Child Left Behind (NCLB) Act of 2001 is the reauthorized version of the Elementary and Secondary Education Act (ESEA), originally passed in 1965 and signed into law by President Lyndon B. Johnson that year. The ESEA is the main federal education law and sets forth the conditions under which local public schools and districts receive federal aid. The terms of the law are revisited every 7 years, the most recent revision being passed by Congress in 2001 and signed into law by President George W. Bush in 2002. NCLB has defined and redefined all forms of public school curriculum design and development and has transformed contemporary directions of research in the field of curriculum studies.

The changes from earlier reauthorizations was generated by frustration that the ESEA, originally a part of the Great Society, seemed to be ineffectual at bringing about authentic change in schools. There has been apparently little impact on those populations that the law was designed to benefit, specifically the children of the poor and people of color. Internationally commensurable studies of student achievement such as the Third International Mathematics and Science Study (TIMSS) and the National Assessment of Educational Progress (NAEP) made clear that in comparison with children from other nations, U.S. students were performing poorly at best.

Great volumes of educational criticism and critique have been generated in recent years with many of curriculum studies leading spokespersons—Deborah Meier, George Wood, TheodoreSizer, and Linda Darling-Hammond—actively and publicly involved in activities of opposition and protest.

### Transparency

The great curriculum projects of the past such as the Eight Year Study were public events in which

teachers worked together to build the frameworks that were to drive great teaching and learning. Even the day-to-day school curriculum is a public thing in that curriculum programs are purchased or developed publicly. Teams of teachers convene to examine curriculum and instructional materials to ensure that such materials are appropriately aligned with state standards. Teachers work together over summers to prepare units and lessons that will be enacted during the school year. However, once the teacher takes responsibility for the curriculum, its public persona is transformed into a private enterprise. Individual teachers even at the same grade level pursue their own vision of instruction, curriculum, and assessment. The NCLB has the potential to alter this pattern in which public curriculum mutates into a private, almost secret activity.

The NCLB requires that publicly developed standards are to govern the day-to-day work of the teacher. Whatever curriculum is used must be consistent with those publicly displayed standards. All children are to be tested on a regular pattern. Although testing is hallowed by tradition, under NCLB, such testing must be aligned with the instructional goals derived from the standards, and more importantly, the results of such testing are both public and open. In the past, schools were able to bury their failures in the “average” of all the test scores from a cohort of students. Under NCLB, test results must be reported by subgroup, for example, English language learners (ELL). The test results must be publicly reported so that the results for all subgroups are presented. Finally, there is a standard metric for identifying the progress for students over time. To comply with NCLB, a school must demonstrate that each subgroup represented in the school has made “adequate yearly progress.” The measure adequate yearly progress (AYP) asserts that children should have the opportunity to learn what has been defined by the standards each year so that when the student is ready to go on to the next grade level or school, he or she knows what is required to be successful at the next level.

These four NCLB imperatives—public standards, public tests, public accountability, and a common and public metric for progress—have the potential to transform curriculum studies. The

public curriculum discourse, though producing new ideas and approaches, is crippled by the fact that the enactment of curriculum has been a private act. There are signs that the habit of private enactment is changing. The new emphasis on professional learning communities is one such sign. The requirements of NCLB provide the incentives to make the entire curriculum enactment cycle transparent.

Yet, NCLB has also proved highly controversial because it has expanded significantly the federal government’s role in education by establishing three NCLB mandates—accountability for results, highly qualified teachers (HQT), and scientifically based instruction (and research)—causing public outcry and leading to carefully articulated criticisms of NCLB-generated practice.

## NODDINGS, NEL

---

Nel Noddings (1929–), U.S. philosopher of education, is widely recognized for contributions across her illustrious career to curriculum conception and reform. Across her writings, curriculum has always held pride of place; for her it is the backbone of schooling. And in effect, no reform should be undertaken without its specific attention. Emblematic of this curriculum emphasis, in 2000, Division B, Curriculum Studies, of the American Educational Research Association, awarded

Noddings its Distinguished Career Award. Central to an international reputation, her prose is direct, pithy, and accessible, and is thus useful to scholars and practitioners alike. Occasional paraphrasing from key texts is sprinkled throughout this entry.

Noddings's biography mirrors her general commitment to education through a multiplicity of opportunities and based in the contributions of each individual to a democratic society. From working-class roots, she earned undergraduate, masters, and doctoral degrees from Montclair State, Rutgers, and Stanford universities, respectively. Her professional life began as a mathematics teacher, curriculum developer and school administrator, and college instructor. A faculty member at several institutions, her principal tenure was at Stanford University as assistant and full professor and as a dean. She often taught courses that focused on or included curriculum theory and application. By 2008, she was the author of 16 books and had published individual pieces almost too numerous to count. She is also a frequent speaker in the United States and elsewhere. Among many honors, she was elected president of the National Academy of Education, the Philosophy of Education Society (North America), and the John Dewey Society.

From a beginning in mathematics education, Noddings's curriculum interests have developed in support of a comprehensive reform position for schooling and education broadly. A basic premise is critique of today's dominant standard and standardized liberal arts curriculum. This is because no persons are exactly alike and schooling should not support such an explicit or implicit agenda. Instead, there should be a rich array of attractive curricula and facilitation for informed choices by students.

Moreover, although predominantly employing language of needs and wants rather than rights, she posits that the present age of "accountability" has meant unrealized equal outcomes and continued inequity. Societal resources matter as does continued discussion of aims of education. For Noddings, aims, accountability, and opportunity become matters of ethics. Both for individuals and society, the general model is one of relation and encounter. The ethical ideal is relations between persons in ordered pairs that are extended to relations with others. Noddings poses that education for ethics occurs for the young through well-chosen

encounters and their effects to trigger deep affect. Genuine relations through genuine encounters multiply.

Across writings, educational and curriculum reform is substantiated through a set of thematics. Surely not exhaustive of curriculum topics, they include her position toward mathematics, proposal for a broad vocationalism, specific focus on the personal lives and everyday interests of children and adults, and attention to the contributions from women's culture for the benefit of everyone. First, Noddings loves mathematics (for many years, a small blackboard principally for working math problems was prominent in her Stanford office). The educational point, ironically and significantly, is that for her everyone need not love mathematics and there should be no strict, narrow requirements for mathematics for everyone. As one outcome of student choice and curriculum differentiation, Noddings offers a general proposal for schools to promote happiness. One arena of personal happiness is preparation for work, as the second theme and as a broad conception of vocation in the curriculum. As across much of her theorizing on curriculum, she begins with critique of existing practices. In this case, schools seem to have forgotten that work is for more than economic preparation. A much-needed curriculum reform is to educate for a wide set of occupations—to appreciate any honest work and to be exposed to and explore many kinds of formal and informal work in the curriculum.

A third thematic is concentration in the curriculum on personal life in the everyday interests of children and adults and particularly in open discussion of different views about them. A recent book on "critical lesson" attends to such everyday matters as home, parenting, religion, and war that are rarely if ever considered. Again for emphasis, Noddings supports preparation for life in a liberal democracy through choice among rich course offerings. Principles of curriculum organization (here at the high school level) include sequential study and location of these topics within the culture of the disciplines, and from these origins, practical applications to everyday use.

Finally, this entry would be remiss without mention of Noddings's feminist theory, tied to leadership and major contributions to an ethics of care. Valuing women's culture in the lives of everyone,

this is the fourth curriculum theme. In earlier writings, she proposes specific study of caring—for self, intimate others, and strangers; for animals, plants, nature, and culture; and for ideas. A later emphasis has been on incorporating the historically significant interests, daily lives, and work of women. As she puts this, in making women’s traditions significant in curriculum, one can start at home. Armed with diverse but ideal conceptions of home, the educational process is to move outward to learn what it means to be cared for, to care for close others, and finally to care about those distant. Women’s private occupation of caring thus becomes public commitment. Across her career, in sum, attention to ethics in society, schooling, and especially to curriculum has been the foundation of Noddings’s significant philosophical contributions.

## NULL CURRICULUM

---

The concept of the null curriculum initiates a critical analysis of curriculum that explicitly seeks to attend to that which is absent, left out, and overlooked how curriculum is conceptualized, created, and enacted. The null, or nonexistent, curriculum, in directing focus on what is *not* present, brings to the field of curriculum studies an

important theoretical tool for considering that which is *not* offered to students, and the potential educational significance and effect of such neglect. As such, the null curriculum keeps alive the classical curricular concern and question most famously expressed by Herbert Spencer in 1860—“What knowledge is of most worth?,” alternately asking what of worth has been unaddressed, left out of what constitutes knowledge, in the curriculum. Additionally, here the null curriculum raises awareness about the deliberative nature of curriculum work itself, by which selections are made and omissions committed ceaselessly based on decisions regarding what is valued, or not. In its explicit address drawing attention to the curriculum that is not, was not, but could have been, the null curriculum also implicitly offers scholars in the field an interpretive impetus for imagining possibilities for the curriculum that might be.

In his 1979 analysis of the “educational imagination” at work in designing the curricula of schooling via its program offerings, Elliot Eisner coined the term *null curriculum* to identify one of three forms of curriculum he posited the school “teaches” its students. Distinguishing the null from the curriculum explicitly introduced and that offered implicitly, in describing a curriculum constituting what schools do not offer to or do for students, Eisner highlights the intellectual perspectives and processes unavailable to them, and raises questions about the educational significance of what is left unattended via schooling, of what is taught by omission, *in absentia*. He notes how, for instance, visual and metaphorical thinking is neglected in favor of verbal and logical reasoning—also calling attention to the art implicit in curriculum work, which requires imagining what is not present as if it were, to better understand and transform what is.

A source of debate, the emergence of the null curriculum concept can be situated within a larger call for reform, begun in the 1960s, aimed at inquiring into how schools overtly, tacitly, and unintentionally fail students and systematically produce consequences of ill-effect. Postulating a formally authorized curriculum and attempting to identify other curriculum forms operative in relation to it—unsanctioned, yet influential and enduring in effect—this criticism has generated a variety of curriculum distinctions for analysis, that is, the

unstudied, unwritten, lived, and hidden curriculum. The null curriculum, among them, has been called ambiguous and operationally indefinable, but its usefulness as an analytical and speculative device is largely acknowledged nonetheless. This has brought into view much that has been formerly ignored and generated new alternatives for curriculum thought and practice for consideration. Scholarship issuing from the null curriculum has explored broad educational exclusions with respect to social class, race, and gender, for example, as well as particular silences, such as neglecting the Holocaust in school curricula. Extending Eisner's academically oriented conception, such scholars have suggested that the null curriculum consists largely of those aspects excluded from the curriculum because of emotional content or potential conflict, reflective of differences in basic values, and beliefs about the purposes of schooling.

The null curriculum foregrounds these important questions in the field of curriculum studies concerning how we define curriculum itself, and to what ends. Some argue that it brings into relief, too, the abundance of confusion and disagreement among scholars on these points. Reflecting a historical shift in focus on the development of curriculum to its analysis, the null curriculum also

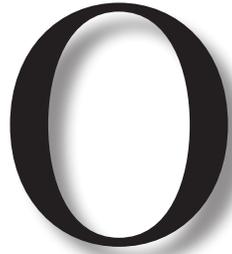

portends the abiding significance of addressing the context in which curriculum is created, having foreshadowed and informed the canon debates, multicultural initiatives, and inclusion efforts deemed so fundamental to present work in the field. The null curriculum continues—given marked educational inequity, an unprecedented explosion of knowledge, and an increasingly diverse, global scene, wherein at issue is not only *what* knowledge is of most worth, but also *whose* and *for whom*—to make its contribution to the field in addressing these vital concerns.

## OBJECTIVES IN CURRICULUM PLANNING

---

Objectives are statements that describe the endpoints or desired outcomes of the curriculum, a unit, a lesson plan, or learning activity. They specify and describe curriculum outcomes in more specific terms than goals or aims do. Objectives are also the instructions or directions about what educators want the students to be able to do as a result of instruction. Considered essential to goal setting and planning curricula, objectives aid students, teachers, and parents by specifying the direction of the curriculum and goals. Typically written by school districts, schools, and individuals, objectives also help ensure that educational processes are aligned and that instructional activities are directed toward the defined outcomes or learning.

There are several criteria for ensuring the appropriateness of objectives. Objectives must be developmentally appropriate and attainable by students within a short period. They must be properly sequenced so that prerequisite skills are accomplished before those objectives that require more complex skills. Objectives must be in harmony with the overall goals of the curriculum as well as with the goals and philosophy of the institution.

Objectives are generally considered the most specific aspect of the curriculum following the philosophy, aims, and goals. The philosophy of education is the mission of the overall curriculum or content area, and aims identify the overall direction of the curriculum. Goals are broad statements

that indicate the long-term outcomes that educators hope to achieve. For example, a school may state that its long-term goal for first graders is that they will be able to read. A corresponding objective might be that first-grade students will be able to read a 100-word developmentally appropriate passage orally with five or fewer mistakes. Thus reading instruction might be developed around enhancing the students' decoding skills, sight-word recognition, and developing oral fluency. In this manner, objectives indicate the lesson outcomes and help communicate the intention of the teacher's instructional strategies. Objectives also assist educators by helping them (a) focus instructional planning, (b) plan appropriate instructional activities, and (c) create or develop valid evaluation procedures. Objectives also signify to students what behavioral changes or observable actions teachers expect them to demonstrate as a result of the student-teacher interactions. Objectives may also provide a rationale about why particular learning activities are used.

Objectives can specify behavioral or nonbehavioral outcomes. Behavioral objectives are written in terms of specific and observable behaviors. Supporters of behavioral objectives favor observable behaviors because they are measurable, unambiguous, and useful toward guiding instructional activities. Behavioral objectives easily and clearly communicate desired target behaviors. These types of objectives are written using verbs that indicate measurable or observable behaviors such as "state," "recognize," "evaluate," or "create." Behavioral objectives guide the development and design of the

curriculum planning by suggesting a sequenced, precise, and compartmentalized approach to actions and outcomes. Nonbehavioral objectives are written using such words as “know,” “understand,” and “appreciate.” Nonbehavioral objectives allow for a more open-ended curriculum and integration of subject matter.

Those who oppose the use of preformulated objectives claim that behavioral objectives limit learning opportunities and activities to only those that can be measured and, thus, ignore the affective and spiritual dimensions of the students. For example, not all educational activities, such as a field trip to swim with the manatees have preformulated objectives, yet this does not mean that this experience was not fruitful or educative.

Educators who decry the unrelenting force and narrowness that a single view of what counts as legitimate suggest that if there is only one correct way to do something, others who hold other values or perspectives are likely to be left out of the educational process. This criticism is amplified by the use of criterion-referenced tests that reinforce an emphasis on limited conceptions of objectives.

Teachers can use three domains of learning when planning curricula, defining goals, and writing objectives. Written objectives can be classified into the cognitive, affective, and physical or psychomotor domains. Traditionally, curricula have been written to reflect an emphasis on the cognitive domain. These classification formats help teachers organize learning activities and the objects of phenomena into a hierarchical order. Each taxonomic level specifies skills, competencies, and understandings that define the outcome. Benjamin Bloom developed the well-known cognitive domain taxonomy. His revised taxonomy has been organized into six levels: remember, understand, apply, analyze, evaluate, and create. The taxonomy is incremental. Skills and competencies build on the preceding level of skill development. Taxonomies have been developed for the affective and physical domains also. They are useful for developing and writing educational objectives that designate different levels of accomplishment.

Although objectives may be written in different ways, they generally have three distinct and descriptive parts: (1) the student task, (2) the conditions under which the student is required to perform the task, and (3) the performance standard. The task

is written clearly so that the student knows what he or she is required to do. Second, the conditions are specified and may include the materials that students will use, the number of minutes allotted to complete the task, or identification of the type of task such as homework, quizzes, or individual assignments. The performance standard identifies the level of achievement that the student must demonstrate to clearly meet the objective.

When creating objectives, particular attention must be paid to matching, worth, wording, and appropriateness. Objectives should match and relate to the goals and aims from which they are derived. Educational objectives should be worthwhile to the student’s present learning needs and have utility beyond the required task. Educators, supervisors, and students must be able to comprehend the written objectives in such a way that the objective is only open to one interpretation. Appropriateness refers to the degree of attainment because not all students need to attain the same learning outcomes.

## OFFICIAL CURRICULUM

---

The official curriculum can be simply defined by the way curriculum itself has been traditionally understood: as the course of study, body of courses, or program of training at a school or university. However, this conception fails to address its analytical significance in the field of curriculum studies, where attention is directed specifically at

what is formally sanctioned by schools or other institutions of learning through their explicit educational offerings. To speak of the official curriculum is also to raise questions about the relationship between knowledge and power, ideology and institution—the politics of education and teaching, and processes of standardization, legitimation, and accountability that come to define what constitutes curriculum. Representing an authoritative response to the classical query concerning what knowledge is of most worth, whether actively endorsed or critically interrogated, the official curriculum affords an object of analysis for clarifying educational purpose and responsibility, providing direction for instruction and assessment, and articulating the meaning of educational success.

Since the unofficial emergence of the curriculum field with Franklin Bobbitt's 1918 publication of *The Curriculum*, many scholars have sought, in defining curriculum, to address such concerns and expand upon understandings that are limited to that which is explicitly authorized. Making curriculum distinctions via descriptors such as *official*, *hidden*, *informal*, or *enacted*, curriculum scholars seek to challenge the tenacity with which traditional notions of curriculum, confined to the formal, have held sway and remain dominant in educational thought and practice. Much attention to the official curriculum, then, has been oriented around its exploration in relation to the “unofficial,” that which falls outside curriculum so narrowly conceived.

David Hamilton reveals, however, the officiating function curriculum has served since its introduction into an educational context in the 16th century. Locating the first such use of the word *curriculum* in an administrative effort of authorities to bring order to the programs of study offered in the universities of Northern Europe during the Protestant Reformation, he elucidates the ways in which social and political forces direct how and what curriculum is officially established, and to what ends. Focusing on a more contemporary—and U.S.—context, Herbert Kliebard documents a history of struggle over authorization of the official curriculum among various groups representing conflicting interests and differing ideological commitments. Encompassing complex compromises and even contradictions among competing constituencies, the curriculum as

formalized, rather than neutral or given, is shown to be a result of deliberation, and even under negotiation.

Michael Apple has done much to direct attention to the official curriculum, specifically his analysis of the “official knowledge” subscribes and promulgates via schooling. Apple's critique posits that these struggles and negotiations are, in fact, obscured, and myriad ideological endorsements unexamined, in a presentation of the official that lays claim to objectivity and common sense. Rather, such claims are powerfully operative in cultivating taken-for-granted policies and practices in education that are profoundly value laden and politically motivated. For example, he lays bare the politics of the adoption of textbooks in the United States. Analyses of authorized textbooks, state curriculum standards, and federal educational policies have also been similarly initiated, to uncover the ideological positions authorized in them and explicate what knowledge is privileged, devalued, or excluded by official definition. For Apple, what is sanctioned is democracy as dominantly defined by the free market, citizenship as conceived in the individual consumer, and knowledge valued as a commodity.

With heightened concern and controversy regarding accountability in education—particularly via high-stakes testing and scripted curriculum, and shifts in the capacity and control of knowledge production via globalization, the official curriculum promises to hold continuing and contested interest and importance for the field. What scholars share is a recognition that the official curriculum lies at the heart of schooling, communicating the most important messages to youth about what we value and why we educate, and thus is of abiding significance as an object of study and potential reform.

## OFFICIAL KNOWLEDGE

---

Official knowledge is the explicit academic content that students are intended to learn and the often-implicit social content that both lies within and contextualizes academic content. Because of its particular blend of academic, social, explicit, and implicit knowledge, official knowledge shares its borders with at least the following three central aspects of curriculum studies: (1) hidden curriculum, (2) formal curriculum, and (3) institutionalized text perspectives. This entry focuses on questions of knowledge and its reproduction through the processes of schooling.

Over 130 years ago, Herbert Spencer wondered what knowledge is of most worth, a question that has served as a touchstone for inquiry about the content teachers deliver and students learn in schools. Official knowledge can be understood as a given society or culture's responses to this question. The field of curriculum studies understands knowledge to be socially constructed. Because official knowledge represents the academic content that those with the power to decide what successive generations of a society should come to understand as important, official knowledge embodies dominant norms and values.

Concerns about dominant norms and values fall into two categories. On one hand are concerns about the ways in which dominant ideas and ideals reify existing sociocultural and socioeconomic categories in their own image. Through this process, people (in this case, students) who most resemble those in power have the greatest likelihood of finding their ways of being and knowing represented in school. On the other hand are the ways in which dominant norms and values reproduce particular constructions of knowledge. As with all standardized versions of knowledge, it is not simply the categories around and through which students come to know about their worlds, it is the content itself.

Michael W. Apple's *Official Knowledge: Democratic Education in a Conservative Age* is

perhaps the most well-known work in curriculum studies on this topic. Apple shares with many curriculum scholars an understanding of curriculum and knowledge as a social construction. From this perspective, knowledge and curriculum are decisions about what "counts" as important information from myriad possibilities, a selective tradition rather than a listing of infallible truths or facts. In this text, Apple traces how a coalition of not necessarily commensurate conservative groups have worked at realigning what education reform means, who is responsible for current educational failures, and the solutions for such educational failures that their reforms provide.

Central to Apple's argument is an understanding of changes in how equity is conceived by this coalition. Instead of being seen as related to oppression and marginalization of *groups*, equity is constructed as a need to guarantee *individual's* rights within a social, economic, and educational free market. Through this lens, educational problems are recast as individual shortcomings without regard to the sociocultural, economic, or other contexts that affect the knowledge students receive in schools.

Solutions for such shortcomings are often provided through a seemingly contradictory motion of tightening what knowledge means and how it is measured while increasing the private (business) sector's access to children in schools and the construction of what knowledge means for students. This pincer-like motion has created the space for ideas such as school vouchers where parents can use public monies to send their children to private schools; standardized assessments that create a mask of objectivity through which nonmajority populations are constantly measured as intellectually deficient; and multiple points of entrée for business into schooling. Apple argues that such movements are possible because they resonate with U.S. common-sense understandings of schooling and the ideas that have in many ways often been present throughout the history of education in the United States.

The seemingly common-sense nature of dominant norms and values and the notion that such understandings have always been present are shared in many scholars' talk about and around official knowledge. For example, scholars such as Ray Rist, Harve Varenne, and Ray McDermott

present a powerful argument about the construction of schooling as a success and failure binary. Rather than possessing inherent traits that render them as successes or failures, such scholarship argues that students are acquired by the sociocultural contexts that surround them—contexts that reflect dominant norms and values that reify existing constructions of what school knowledge means and who counts as successful. Similar to Pierre Bourdieu’s construction of *habitus*, these authors contend that the injustices of this construction that unfairly measure students against one another are perceived to have been *always already there* and therefore often go unquestioned.

Predating *Official Knowledge* by more than 20 years, Michael F. D. Young’s edited volume *Knowledge and Control: New Directions for the Sociology of Education* contains many of the themes and perspectives central to what has come to be called *official knowledge*; Nell Keddie’s chapter on “Classroom Knowledge” is but one strong example. The topics and ideas presented in this volume are particularly prescient, noting the common-sense nature of knowledge, how knowledge is normative, as well as some of the ways in which such normalization positively affects some students at the expense of others.

In sum, *official knowledge* is the term used in curriculum studies to indicate academic and social content that is important to the dominant group that has the power to construct knowledge in its own image. Although this knowledge may well indeed be important to a given society or culture, official knowledge also reifies sociocultural and socioeconomic divides. As the scholars presented in this entry demonstrate, these divides tend to consistently disadvantage nondominant groups while maintaining the dominant group’s dominant status.

## OHIO STATE UNIVERSITY COLLECTIVE OF CURRICULUM PROFESSORS

---

During the tenure of Dean George Arps of the College of Education from 1920 to 1937, individuals and projects came together that set the course for curriculum studies at Ohio State University for nearly 60 years. The people included Boyd H. Bode, W. W. Charters, and Laura Zirbes. Arps lured Bode, a distinguished philosopher, to Columbus, Ohio, and to education in 1921. Three elements of Bode’s philosophy shaped the pattern of curricular thinking that emerged in the college. Bode argued that curriculum development necessarily requires both a theory of mind or intelligence and a social theory, that the two necessarily go together. These elements were joined by a third, general education as that education essential to learning the ways of democracy required by all students. Bode argued that every aspect of schooling taught a way of life and that way of life should be explicitly democratic.

Charters came to Ohio State University in 1928 to direct the Bureau of Educational Research. Charters’s model of curriculum development, known as job or activity analysis, began with determining ideals and activities arising from good performance of the many activities of life. These were analyzed into units to be arranged logically and prioritized according to importance and time availability. Next, the best approaches to teaching the ideals and activities were identified and, finally, ideals and activities were arranged in an order that most suited the material and how children learn. In contrast to Bode, Charters asserted that ideals were objective and enduring.

Zirbes also came to Ohio State University in 1928 where she served as professor of elementary education. Within the college, Zirbes elevated the importance of school experimentation, founding a summer demonstration school to develop and test progressive practices in the classroom and later serving as director of research within the laboratory school. Her use of workshops and various experimental classroom practices served as venues for exploring the educational implications of democracy at the early childhood and elementary school levels. Additionally, she championed aesthetics and in her own practice modeled creativity as essential components of effective teaching.

Ohio State University housed the Eight Year Study. As a member of the directing committee, Bode brought to the forefront democracy as a guiding ideal, a position Charters came to embrace. The Ohio State University School, one of the participating 30 schools, was founded explicitly to test Bode's theories of education. Opening in 1932, the school and several of the later directors gave leadership in developing the programmatic implications of democracy as a way of life and, in varying degrees, experimentalist conceptions of mind.

Bode, Charters, Zirbes, and the activities of the Eight Year Study profoundly influenced the history of curriculum across the nation as well as at Ohio State. Charters brought Ralph W. Tyler to the Bureau in 1929. Occupying offices across from one another, Bode knew of Tyler's innovative approaches to assessment. Tyler was appointed in 1934 to direct the evaluation of the study, an experience that would significantly shape his curricular thinking. When one reviews the Tyler Rationale, the influence of both Bode and Charters is apparent—Charters's in its logic and Bode's in the place given to philosophy and learning theory. Zirbes was a guiding force behind the University School, considered one of the six most experimental schools participating in the Eight Year Study.

Charters's interests are also apparent in the curricular work done within the college on the use of radio and other media to facilitate learning. Here, two members of the bureau, I. Keith Tyler and Edgar Dale, both close associates of Charters, are important. A third member, Ross Mooney, pioneered independent work in creativity, perception, and adult development that later stimulated criticism of established technical approaches to

curriculum development. After Tyler's departure in 1938, others associated with Charters and the Bureau continued innovative work in curriculum evaluation and assessment.

Each of the elements of Bode's thinking shaped several of his students' careers. A leader in the study and, from 1938 to 1941, the director of the University School, Harold Alberty became a major proponent of core programs for general education. Following publication in 1947 of the first of three editions of *Reorganizing the High School Curriculum*, Alberty's needs and social problems-based core became increasingly influential nationally. Working as a teacher in the University School and later as a curriculum associate within the study, H. H. Giles, who studied with both Charters and Bode, pioneered teacher-pupil planning, an essential aspect of successful core programs and key to developing the qualities of democratic citizenship. Of Alberty's many students, Paul R. Klohr, University School director from 1952 to 1957, and William Van Til, a core teacher and later distinguished professor, continued to develop the core curriculum. Later in his career, Klohr encouraged the formation of "the reconceptualist movement" in curriculum studies that is associated with his student William Pinar.

Bode's influence flowed directly through his student Alan Griffin and Griffin's many students, three of whom taught at Ohio State for many years: Robert Jewett, Frank Buchanan, and Eugene Gilliom. Lawrence Metcalf and Maurice Hunt, also Griffin students, grounded their text, *Teaching High School Social Studies*, in ideas presented in Griffin's 1942 dissertation, *A Philosophical Approach to the Subject Matter Preparation of Teachers of History*. Coming from Bode, a central idea developed by Griffin and embraced by these authors was the opening of closed areas of social life, including student beliefs, to reflective inquiry and to the connecting of beliefs to social issues to further democratic social theory.

Professors of curriculum associated with Ohio State also are important in the history of the Association of Supervision and Curriculum Development. Several Ohio State professors and former graduate students served on the executive committee and as association presidents including William Van Til, Kimball Wiles, Arthur Combs, Harold Shane, Alexander Frazier, and Jack Frymier

in the 1960s and 1970s. Frymier came to Ohio State in 1962 and retired in 1984; while president, he initiated the School for Tomorrow project, which led to development of the Annehurst Curriculum Classification System, a delivery system for managing materials and individualizing instruction. Although supportive of the value of philosophy in curriculum development, Frymier's work signaled a break from earlier traditions.

## ONTARIO INSTITUTE FOR STUDIES IN EDUCATION COLLECTIVE OF CURRICULUM PROFESSORS

---

Since its founding in the late 1960s, the Ontario Institute for Studies in Education (OISE) at the University of Toronto has been a resource for study of how curriculum is implemented and enacted by teachers and interpreted by students through the innovative scholarship of Michael Fullan, F. Michael Connelly, John P. Miller, Roger Simon, and D. Jean Clandinin. A cadre of graduates expanded applications of the narrative inquiry to new populations and cultures.

A graduate of the University of Toronto with a doctorate in sociology, Fullan served as dean of OISE and as policy-implementation advisor to the Minister of Education and Training in Ontario.

Fullan has been internationally recognized for his study of institutional change and the factors that promote or inhibit sustained reform. Fullan's initial interest in this subject was study of curriculum implementation and why various curriculum innovations of the later part of the 1960s and into the 1970s never became standard practice in elementary schools. In a review of research with Alan Pomfret, Fullan described the complexity of the process of translating a curriculum reform into lived practice, contingent on the character of the reform (clarity, complexity), the strategies used to implement the change (professional in-service, resources), the character of the unit that is implementing the reform, as well as the character of the macropolitical unit that promoted the reform. Fullan's studies evolved from investigation of the process of curriculum change to considerations of when institutional change can be regarded as successful reform by achieving and sustaining its goals. For the past four decades, Fullan has examined various enacted curriculum implementations and served as authority, counsel, and critic of variations on how to realize curriculum reform. His own proposal, in working with Ontario elementary schools, is that the classroom is the most effective unit for effecting change, with curriculum innovation personalized to the needs of each child. Curriculum and instruction are developed to these needs, however, without hardwiring a curriculum that is teacher-proof, and supported by a system of professional learning for teachers that is relevant, evaluative, and directed to regularize the reform in classroom practices.

F. Michael Connelly came to OISE shortly after its establishment as a graduate studies program, having completed his doctorate at the University of Chicago where he studied with Joseph Schwab, Benjamin Bloom, and Philip Jackson. Initially focusing on curriculum planning and improving science education, Connelly's investigations brought him to consider what a curriculum became and meant when intersected with the lives of teachers. Interest in expanding the conversation on ways of studying curriculum prompted Connelly to found and serve as initial editor of *Curriculum Inquiry*. In collaboration with his student D. Jean Clandinin (University of Alberta), Connelly developed a model of inquiry that used narrative to explore the ways that knowledge was organized

and integrated by teachers. Through examination of diverse artifacts, they sought to provide a credible, defensible description of how curriculum became realized in the classroom. Using professional artifacts, interviews, conversations, and most particularly through storytelling and re-telling, teachers were encouraged to craft an awareness of and relate their decision-making processes. Through these studies, how individual teacher knowledge constructs and experiences continually interact to inform and transform curricular practice was revealed. With this examination of teachers' knowledge came the conviction that narrative is a primary organizer of knowledge, a method of storing and retrieving professional insights that is able to convey emotional context as well as guiding principles and schemes for situational problem solving.

In addition to the direct influence of Fullan, Connelly, and Clandinin on curriculum studies, John P. Miller has been a leader in the promoting of the holistic education movement, integrating wisdom traditions, spiritual awareness and alternate modes of knowing into teaching of the humanities. Roger Simon offered an ethical argument that teachers be aware of their role as cultural workers and consider the social import of their labors with learners, exploring tacit ways that social transformation is either limited or promoted. Jim Cummins has been a major contributor to the development of bilingual education and education in a multicultural society.

## OPEN CLASSROOM AND OPEN EDUCATION

---

Open education is a theory of education based on the principle that education and its curriculum should be active, fluid, and individualized. The primary concern of open education is to facilitate meeting educational goals while fulfilling the unique, individual potential of each child. Open education is particularly relevant to curriculum studies because of this flexible format. Originating out of various grassroots communities, open education incorporates many differing theories of education. It is sometimes referred to as *informal* education.

Modern open education in the United States has been greatly influenced by the primary education system of England. During an educational revolution after World War II, many English educators began incorporating ideas that would later become open education. In 1967, the English minister of education commissioned a report assessing aspects of primary education and called attention to changes made using open education approaches, urging all other schools to adopt similar practices. This report was commonly known as the Plowden report. Its observations influenced many educators, including the early childhood educator, Lillian Weber. Having visited England, Weber returned to the United States an advocate for open education, directing further influence toward open education. Likewise, Canadian politician Joseph Featherstone brought attention to the open education system in a series of articles for *New Republic* in 1967. Since that time, England has incorporated open education into its nationwide program. Conversely, open education in the United States has been confined to private and laboratory schools, reaching its peak popularity in the late 1970s to the early 1980s.

A description of an open classroom appeared in a 1970 issue of *The Saturday Review*, written by Ronald Gross. This article summarized four basic practices of the open classroom: (1) decentralization and organization of space into smaller, flexible units; (2) encouragement toward individual and group exploration/activity within that space; (3) incorporation of diverse, hands-on educational material; and (4) individual/small-group educator-led instruction.

Curriculum in open education revolves primarily around the individual student. It emphasizes individual interests, and highlights the influence learning materials and their arrangement within a classroom may have upon children. Although the starting point of learning is the children's experiences and interests, this is not by any means the extent of it. Open education is often misunderstood in this regard. Educators in an open classroom may often follow a specific, daily curriculum. This curriculum is supplemented and altered through interaction to complement spontaneity. Therefore, although lessons may be taught and learned, the manner in which they are done so is rarely repeated.

Open curriculum emphasizes context as an integral part of education. To maintain context-given content, open curriculum suggests integration. One section of the Plowden Report, "The Need for Flexibility and Balance," describes how teachers in England have successfully integrated subject-based curriculum into context-based curriculum. Open classrooms, like many of their traditional counterparts, recognize that subject division may obscure context.

Integration may be achieved in numerous ways. Many students and classes choose a specific area of study or problem to resolve. Along with their study, students may write, calculate, and perform any number of experiments or activities ranging through all areas of learning to achieve their objective. With unnecessary barriers removed, subjects such as writing may be taught as tools for learning a subject of interest, rather than as a particular subject to be learned. Often projects are sparked by a first hand experience that children may share in the classroom. Experiences may be spontaneous—such as observing birds from a window, or planned—such as a day trip to a farm. Together, they serve as a springboard for learning, by either generating interest for learning or being initiated by the child.

Although open education and open curriculum have become foundations of learning, individual assessment remains controversial. When evaluating personal progress, many educators rely on performance with standardized testing. Open education educators argue that precisely because of the varied, individual ways children learn, standardized testing is rendered meaningless. Although

the United States was able to observe a model of open education via England, no such precedent has been set for academic assessment. Ronald Gross, in *The Saturday Review*, acknowledged that England has not experienced the same pressure for assessment as the United States has. Although tests and assessments vary, children taught through open education in the United States have performed as well as their peers in traditional systems. Though open education assessments were initially influenced by traditional assessment, the influence of open education back upon those traditional systems can be distinguished today in practices such as portfolio and authentic assessment.

## OUTCOME-BASED EDUCATION

---

Outcome-based education (OBE) is a student-centered, results-oriented instructional system that focuses on those processes by which each student in the school is able to demonstrate what he or she knows and is able to do to a predetermined level of attainment. In its focus on clearly specified student outcomes as the curriculum, OBE differs from traditional education that emphasized school inputs, such as Carnegie units, known as "seat time," as indicators of student achievement. The original conceptual framework for OBE was based in the Benjamin S. Bloom's Learning for Mastery model and in the theoretical work of

John B. Carroll, which asserted that as many as 95% of students could achieve mastery of a topic or a task if differential instruction that maximized the quality of instruction, the understanding of the instruction, and the time allowed for needed instruction was provided to the student.

In the 1980s, mastery learning expanded from individual classrooms to districtwide implementation of the model, and the term *outcome-based education* was adopted to identify this instructional system. In an OBE system based on mastery learning, learning was not a finite resource but was unlimited, allowing the potential of every student to be maximized and not regulated by a belief in the random distribution of intelligence. By the 1990s, many school districts in the United States, Europe, Asia, and Australia were implementing OBE and were reporting gains in student achievement, in particular for lower-income students and for students who were not in the upper 20% of the district student population. In 1992, Pennsylvania became the first state board of education to reformulate its state curriculum to include measurable student learning outcomes, later to be termed *academic standards*.

In an outcome-based system, what the student is expected to learn is clearly identified as an objective/standard and the student demonstration of the learning to be acquired must be measurable. The level of student achievement is measured via multiple assessment means, ranging from selected response tests to performance-based exhibitions. Multiple instructional strategies are used over time until the student reaches a satisfactory level of achievement. The design of the strategies involves an ongoing teacher reflection and analysis based on the learner's needs. The student outcome, the instructional strategy, and the assessment means are clearly aligned in the instructional model.

During the early development of OBE systems, student progress was based on criterion-referenced rather than norm-referenced assessments. Local districts determined the outcomes, the strategies, and the assessments; if required by their state, local student outcomes were aligned with state standards. However, as a result of the No Child Left Behind Act of 2001 (NCLB) and its requirements for state defined academic standards and for state standardized tests to assess student achievement, local districts have had less and less control over

the development of student academic outcomes, the form of assessments, and the design of the instructional strategies.

In the mid-1990s, William Spady and other proponents of OBE developed what they called "transformational" OBE, in which curriculum planners expanded the scope of learning outcomes beyond essential academic knowledge and skills to include higher-order thinking skills, affective values, and social behaviors. Many parents and community members considered the expanded learning outcomes too vague and overly directed at academically average or weak students, and questioned how certain outcomes, for example, the development of student tolerance to diverse groups would be assessed. Their opposition in several states led to a narrowing of learning outcomes and their being renamed "academic standards" and the elimination of psychological or values outcomes. NCLB mandated that each state develop a set of academic standards in reading, mathematics, and science for Grades 3 through 8 and Grade 11; in effect, these standards defined each state's curriculum for these subject areas.

## OUTSIDE CURRICULUM

---

*Outside curriculum* refers to the purport and patterns of teaching and learning that occur in

nonschool contexts of life. As with school curricula, outside curricula could be analyzed in terms of diverse venues: intents or explicit policy dimensions; hidden or implicit dimensions (sometimes referred to as *hidden curriculum*); aspects that are part of the act of instruction, or taught curricula; tested curricula, relatively narrow bands that are subjected to evaluation; learned curricula, or that which is acquired and applied from the educational experience; embodied curricula, or that which becomes part of a person's existence and guides his or her life. Thus, outside curricula are those dimensions of life experience that help shape a person's outlook and ways of negotiating the world. Outside curricula should not be confused with the *extracurriculum*, often referred to as *extracurricular activities*; the latter pertain to clubs and organizations sponsored by schools and often conducted in after-school hours or specially designated times during the school day. Examples of extracurricular activities include band, choir, sports teams, yearbook committees, school newspapers, service organizations, interscholastic sports teams, intramural sports, subject matter clubs, theater and drama, honor societies, and many more. Sometimes extracurricular activities lead students to outside curricular experiences that are totally apart from the purview of the school. This is part of the realm of outside curriculum as treated here.

The literature has more recently referred to outside curricula and *public pedagogy*, in writings of Henry Giroux, Peter McLaren, and others. William Schubert used the term *outside curriculum* in the 1980s, calling first for its study to augment understanding of school curriculum by providing a more complete understanding of each student. What students learn from their home and family, culture, language, community, religion or unbelief, nonschool organizations (from scouts, sports, dance, and music to gangs, peer groups, and other informal relationships), mass media (television, radio, video, videogames, CDs, comic books, magazines, books, and the Internet), jobs or vocations, hobbies or avocations, and more. Illustrative questions follow vis-à-vis the forgoing topics, which are in turn followed by curriculum topics or categories that could be used as a basis for analyzing and interpreting the curriculum implicit or explicit in each.

## Illustrative Outside Curricula

The many ways outside curricula have been conceived are sampled here through illustrative questions. Literatures in sociology, anthropology, political science, history, geography, communication, and the like could be sources of research and theory that could be tapped by those who want to better understand the myriad realms of outside curriculum that influence the growth, understanding, perspective, contributions, and lived experience of all human beings. A central point is that the education of anyone is derived from much more than formal, or even informal, experiences with school curricula.

### *Home and Family*

The curriculum of home and family shapes human beings during their formative years, a phenomenon that many psychologists claim cannot be overestimated. How do families enable children to learn to talk, walk, socialize, pursue their interests, and meet their needs? What consciously orchestrated and unconsciously created configurations of experience derive from homes (or even from homelessness in the instances of the many who have no homes throughout the world) that shape human beings? This pertains to parents, older children and youths, and to members of extended families, as well.

### *Culture*

The values, beliefs, social forms, and ways of living of particular ethnic, racial, or religious groups may or may not be incorporated in the school experience. What happens when school experiences bypass, disconnect, or contradict salient features of cultural curricula in the lives of learners?

### *Language*

When school curricula are provided in a language that differs from a person's primary language, what are the effects? How does minimization of one's principal mode of communication contribute, intentionally or unintentionally, to the colonization process? What limitations in cultural understanding are wrought when a language is

used that obscures understandings only available in other languages?

### *Community*

To what extent is school curriculum in a given community consonant with the outside curriculum of the community that surrounds the school? What is taught and learned if the two are essentially incompatible?

### *Religion*

What perspectives or outlooks are conveyed when school curriculum is supported by a given religion? What are denied? Alternatively, if there is separation of church and state, as in the United States, how does the absence of emphasis on religion, belief, or unbelief shape learners? What formal and informal curricular assumptions underlie teachings of religious organizations? What formal and informal curricula contribute to agnostic or atheistic orientations?

### *Formal Organizations Outside of School*

How do each of the following illustrative organizations influence the character, events, perspectives, and consequential actions of those who participate in them? Boy Scout and Girl Scout organizations have long offered formal curricula that lead to merit or proficiency badges and different ranks to designate achievement. Upon what assumptions do these curricula rest, and more profoundly, what messages are conveyed about service, regimentation, and the like by participation in such organizations? How do the myriad sports organizations, from Little League to the Olympics preparation, shape outlooks and lived values, by the inspiration, activity, and pressure extended to all who participate in them?

Similarly, what is conveyed by experiences provided by organizations that stimulate learners to experience or develop expertise in such organizations? What is learned about a topic being taught overtly, *and* what is learned about values, human relationships, and more? What teaching and learning occur in cultural organizations (such as community centers, museums, YMCAs), and how does this teaching and learning affect participants?

Again, what subtle messages are conveyed as accompaniments to overtly stated purposes?

How does a family history of participation in gangs, the secrecy of their linguistic expressions on walls pejoratively labeled graffiti, hierarchical relationships, experiences of induction and initiation, and modes of evaluation contribute to outlooks of participants? How do gangs represent contestation with and resistance of colonizing efforts of dominant society, and how have some gangs moved into activist spaces and social movements in attempts to acquire greater equity and justice, such as the Black Panthers in America? How do friendships, social groups, peer associations, marriages, acquaintanceships, and other relations shape outlooks and practices?

### *Mass Media*

It can be argued that the most influential curricula in the advanced postindustrial world are derived from mass media. Mass media influence (often via advertising) powerfully seeps into preindustrial cultures as well, often bestowing a globalized mind-set there, too. Such impacts stem, such as the following:

Situation comedies, family shows, music and its messages, talk shows, game shows, well-known personalities, and interpretations of news all shape outlooks, life styles, and even mannerisms. Although impact (and *class size* implications) of intentionally educational shows from *Mister Roger's Neighborhood* and *Sesame Street* to PBS specials and offerings on the Food Channel or the History Channel are powerful, the informal influence of Oprah, Johnny Carson, Barbara Walters, or the many fictional families, hospitals, soap opera relationships, law and crime-fighting groups, and comedy shows, all offer examples of how to think and be, of what to need (in addition to commercials that directly address such matters). How do all of these constitute curricula that shape who we are and who we are becoming?

Virtual worlds of the movies (large and small screen) and participation in videogames and computer games are couched in curricular orchestrations that allow freedoms and pose restrictions. What do they teach—both overtly and by the nature of the learning processes they engender? How do these worlds

influence, shape, control, and release our imaginations about what is or might be possible?

Although print materials (books, magazines, and hybrids such as comics) are diminished by comparison to the myriad images to which we are exposed on a momentary basis; they still have deep impact. Why do so many scientists talk of benefit in formative years from comic books which were considered taboo by their schools? Why do the young rise to the occasion to comprehend *Harry Potter*, the *Lord of the Rings*, Spiderman, and much more of modern and postmodern mythology, while in school the same students are earmarked as problematic learners?

Apart from profound substantive abundance provided by the Web, how has almost universal capacity to access and negotiate information and misinformation affected us all? How has the opening of myriad channels of communication emerged so profoundly with so little direct tutelage, so much informal interaction, learning by trial-and-error, and skill development through careful perception? and by careful perception? Then, how has the accessibility of information regenerated values, capacity for self-education, and communities (actual and virtual) of curricular exchange that saturate human lives with previously unimaginable learning?

### *Vocations and Avocations*

How do jobs experienced and occupations vicariously perceived in others shape our image of the past, present, and possible? From jobs that follow the rules (factory, military, fast food, and service industries) to vocations (including those with immense flexibility or work from home varieties) that deal with the invisible worlds of ideas, commodities, relationships, and values or understandings, how do they fashion outlooks? How do hobbies, from electronics and computers to popular arts, sports, and multifarious relationships create in many (who might otherwise be considered mediocre) vast storehouses of knowledge?

There is considerable overlap among these and related realms of outside curriculum. A central point is that if whole persons are to be educated, then those who develop curriculum in any of these realms must be aware of how those with whom they work are shaped by the other realms.

### **Exemplary Conceptual Schemes for Analyzing Outside Curriculum**

The same categories of analysis may be used to understand outside curricula as are used for interpreting school curricula. Employment of such analytic schemata is a principal basis of how the outside realms become phenomena of inquiry for curriculum studies. Some of the most prevalent conceptual schemes and their founders are illustrated in the following, and make possible diverse interpretations of curricula within the previously mentioned realms of life. For example, John Dewey asks of any curriculum whether it gives credence to the psychological as a starting point. By *psychological*, Dewey meant the interests and concerns of learners, as contrasted with the *logical*, that is, organized bodies of knowledge prepared by experts for dissemination. He advocated that curriculum be initiated through the interests and concerns of learner. Hollis Caswell initiated *expanding horizons curriculum*, that is, a progression from the home, to the neighborhood, community, state, nation, and world. Ralph Tyler developed a rationale that advocated consideration of purposes, learning experiences, organization, and evaluation, advocating that each should be informed by philosophy, psychology, social and political agendas, evolving conceptions of the disciplines, and learner interests and concerns derived from out of school realms of life. L. Thomas Hopkins and Harold Alberty called for integrated curriculum and core curriculum, respectively, each building curriculum from fundamental interests of students is in their own self-development and social responsibility. Jerome Bruner argued that curriculum should be developed according to the implicit structure of the disciplines, and that learners should be immersed in subject matter areas to acquire an intuitive understanding that resembles that of experts. Joseph Schwab admonished curricularists to focus on the enhancement of life in particular practical situations, by eclectically matching of extant knowledge to situational needs, adapting it to situations, and developing one's own capacity to anticipate possibilities. Schwab saw curriculum as a complex and dynamic interaction of four commonplaces: teachers, learners, subject matters, and milieus. Jack Frymier called for curricular attention to artifacts, actors, and events in curriculum. Louise Berman

offered a process-oriented curriculum of new priorities: perceiving, communicating, loving, knowing, decision making, patterning, creating, and valuing, as contrasted with conventional subject areas. In work with Brazilian peasants, Paulo Freire drew a stark distinction between what he termed *banking* and *problem-posing* curricula. He criticizes the former as commodified knowledge for social control, and advocates the latter to unleash insight from within the experiential understandings of people themselves. Like Freire, Michael Apple, Henry Giroux, and other critical theorists ask the following when taking stock of any given curriculum: How is knowledge reproduced? What are its sources? How do learners and teachers resist or contest it? What is realized by participants in the situation? What and whose interests are served? Do such interests liberate, and for whom? Who benefits and who is harmed? How can liberation be enabled for more, even all, of the participants? Kieran Egan suggests an alternative to the expanding horizons curriculum based on mythic, romantic, philosophic, and ironic phases of development. He calls for learning through story, not artificial analysis of concepts de-contextualized from learner experience of learners. William Pinar and Madeleine Grumet call for emphasis on the verb *currere* more than the noun *curriculum* in pursuit of understanding of one's present by excavating one's past and by imagining possibilities for one's future. John Holt and John Gatto have each also directly contributed to a form of curriculum, *unschooling*, that is intentionally or outside school curriculum. William Schubert emphasized that the central question of curriculum studies (What is worthwhile?) be the organizing center of curriculum experienced by learners in any situation. Their growth is enhanced when their learning is guided by asking, What is worth knowing, needing, experiencing, doing, being, becoming, overcoming, sharing, and contributing in my life? Although these orientations to curriculum differ considerably from one another, and although most of them have focused on curriculum in school, they readily can be applied to myriad realms of outside curriculum.

## Uses of Outside Curricula

Understanding outside curricula in any realms of lived experience has consequences for the growth of human beings. In combination with one another, realms of outside curriculum offer a kind of perspective that could be called *ecological*, that is, emphasizing patterns of relationships among environs that create us. Refined understanding of implicit and explicit influences of outside curricula provides more complete conceptualization of human growth and its sources. Although such understanding offers significant bases for decision and action vis-à-vis curricula of schooling, it significantly provides even more potential for illumination of the curricula embedded in a diverse and expansive landscape of human experience that can be called *educational*.

## PARADIGMS

---

The concept of paradigm within curriculum studies, shaped by Thomas Kuhn's influential work *The Structure of Scientific Revolutions*, means a unifying theoretical framework of an academic discipline as well as a worldview. Paradigm shift occurs during times of great intellectual transformation as one paradigm is rejected and replaced by another, this usually taking place over a length of time as the original model becomes untenable in view of disciplinary discoveries and societal changes. Identification of paradigms allows scholars to make sense of their fields, to clarify and create new research questions, and to guide their methods and analyses.

In the field of curriculum studies, paradigms comprise assumptions about learning and teaching, the nature of reality, knowledge, intelligence, inquiry, discourse, the naming of problems and approaches to problem solving, and social and political values. Unlike some academic fields that sanction only one paradigm until another one evolves and wins acceptance, several paradigms have existed simultaneously within curriculum studies; thus, although paradigm development may signify a revolutionary change in thinking, a new paradigm may not replace an existing one. Adherents of a particular paradigm have developed their identities as curricular theorists and researchers from its worldview, characterizing their held beliefs and values in contrast to others and creating among themselves discourse communities. Whereas

paradigmatic conflicts create deep divisions within the field, they also serve as catalysts for vigorous dialogue, ensuring that no one curricular worldview dominates without critique.

Over time, a number of paradigmatic dichotomies and trichotomies have been articulated and invoked within curriculum studies. Such classifications encompass worldviews demarcated by philosophical orientations, cultural traditions, approaches to inquiry, and to curricular development and enactment. Curriculum theorist William Doll, in *A Post-Modern Perspective on Curriculum*, delineated three paradigms (premodern, modern, and postmodern) that characterize major differences that serve as a frame of reference for understanding other identified paradigms within the history and contemporary field of curriculum studies.

The premodern paradigm, emanating from ancient Greek philosophy, sets forth an ideal of order, symmetry, balance, and harmony. The conception of a just and ordered society underlying the early forms of this paradigm presents a conservative worldview of static knowledge and societal hierarchy in which individuals know their place in the social order; however, later incarnations focus on democratic principles and visions. In this paradigm, education consists of striving to learn essential and eternal truths and principles for living out how one lives in the world. Elements of the premodern paradigm are represented in the liberal education tradition although, paradoxically, aspects of this paradigm are found in indigenous worldviews that accentuate harmonious relationships, balance, and respect for elders and their

knowledge. The goal of curriculum studies in this paradigm is the attainment of balance through offering a course of study that aims to create well-rounded, wise individuals. Moreover, educators are paramount in the process of initiating learners into traditions of knowledge and beliefs.

The modern paradigm, often viewed as the dominant paradigm of 20th-century European American education, emanates from Enlightenment philosophy that emphasizes an individualistic, mechanistic, and progress-driven worldview, control and domination of the environment, competition, and directly perceived reality. This paradigm's themes include efficiency, linearity, rationalism, empiricism, scientific method, measured outcomes, and standardization. Descriptions of the modern paradigm focus on an engineered, goal-driven, and segmented disciplinary curriculum, at times portraying students as raw material shaped into products for the benefit of society and industry. At its zenith in the early 20th century, this paradigm included Franklin Bobbitt's industry-inspired notion of social efficiency and scientific management of curriculum to provide what appropriate education to students according to their social classes and apparent abilities. Later, in the mid-20th century, the curriculum-planning model formulated by Ralph Tyler became the dominant way of viewing the curriculum field. In the late 20th and early 21st centuries, this has been expressed as the standardized management paradigm with its emphasis on teaching to meet state and national standards. In this paradigm, the role of educators is to deliver the curriculum and to provide the right experiences so that the prescribed goals—created by others outside of the classroom—are met.

The third paradigm, postmodernism, holds a complex, multifaceted worldview that can be understood as a critique of the elements of modern and premodern paradigms through rejection of both the belief in an empirically known reality and eternal truths. The postmodern outlook suggests the world is not orderly but complicated and unpredictable, that history is not linear and segmented but evolving and contradictory. Postmodernism recognizes multiple truths, the importance of interpreting individuals' personal experiences as well as a multiplicity of perspectives through the lens of race, ethnicity, social class, gender, and sexual orientation. This paradigm also

highlights the social construction of knowledge and emphasizes integrated curriculum, authentic assessment, education for understanding, dialogue, interaction, perspective taking, creativity, and playfulness. As follows, the postmodern paradigm is an umbrella for various curricular paradigms including constructivist, critical, democratic, holistic, ecological, multicultural, and indigenous paradigms. The goal of curriculum studies in the postmodern paradigm, what curriculum scholar William Pinar named as the reconceptualization of curriculum studies, is understanding. Through curriculum inquiry—including qualitative, phenomenological, and hermeneutic research approaches—curriculum is not measured; instead, its complexity is explored.

## PARTICIPATORY DEMOCRACY

---

All schools serve the societies in which they're embedded—authoritarian schools serve authoritarian systems, apartheid schools serve apartheid society, and so on. Practically all schools want their students to study hard, stay away from

drugs, do their homework, and so on. In fact, none of these features distinguishes schools in the old Soviet Union or fascist Germany from schools in a democracy, and indeed those schools produced some excellent scientists and athletes and musicians and generals. They also produced obedience and conformity. In a democracy, one would expect something different and something more—a commitment to free inquiry, questioning, and participation; a push for access and equity; a curriculum that encourages independent thought and singular judgment; a standard of full recognition of the humanity of each individual.

The core lessons of a democratic education—an education for citizenship, participation, and active engagement—include these: Each human being is unique, induplicable, and of incalculable value, and everyone has a mind of his or her own; we are each a work in progress swimming through a dynamic history in the making toward an uncertain and indeterminate shore; we can choose to join with others and act on our own judgments and our own imaginations; human enlightenment and liberation are always the result of thoughtful choice and action.

There is a more fundamental purpose to public schooling in a democracy than either loyalty to the state or fealty to the leaders or job training, and that is teaching citizens to think about the issues that affect their lives and how they might act to change things. Pressure from government to make schools little outposts of patriotism and military recruitment, or from business to make the goals of education identical to the needs of corporations jeopardizes the democratic foundations of education. We must ask ourselves whether schools geared to preparing loyal subjects or obedient workers also build thinking, literate, active, and morally sensitive citizens who carry out their democratic responsibilities to one another, to their communities, to the earth.

Students in a vital democracy must learn the values of self-governance: to care for other people; to accept wild and vast diversity as the norm; to acknowledge that the full development of each is the condition for the full development of all; and to value participation, free thought and speech, civil liberties, and social equality. Curriculum that contributes to these commitments involves analysis and exploration, diverse political expression, and independent thought and action.

Participatory democracy rejects formal and structural markers of self-governance in favor of a system based on people actually making the decisions that affect their lives. Voting is surely an important right, for example, but it is not, in and of itself, a singular or sturdy marker of democracy. Again, Nazi Germany, the Soviet Union, and Baathist Iraq all held elections, but none was a recognizably democratic society. In our own country, we've seen elections stolen and manipulated, voters disenfranchised and their rights suppressed, electoral colleges overturning the popular vote. This is all to say that elections may be a necessary aspect of democracy, but they are also by themselves an insufficient expression.

Participatory democracy insists that the people themselves must decide. Mass society is itself, then, an obstacle, the manipulation of media a barrier, huge amounts of money a hindrance, bureaucracy, hierarchy, command-style organization an obstruction. So is the pressure of the monoculture, the power of the monologue, the symbol of the talking head. Participatory democracy at its heart requires dialogue—each one speaking with the hope of being heard, and each one listening with the possibility of being changed.

Democracy in the United States has been predicated on citizens' informed and thoughtful engagement in civic and political life, and schools have been essential to the development of such citizens. But the foundations of democratic engagement— independent thinking and critical analysis, for example—are always in contention, generally under attack from some quarter or another. Participatory democracy requires a high level of vigilance and action in its defense, and in its enactment.

## PEABODY COLLEGE COLLECTIVE OF CURRICULUM PROFESSORS

---

Since its founding in 1914, George Peabody College of Education has been a principal center of graduate study in education in the South, affecting curriculum studies through the work of Hollis Caswell, Harold D. Drummond, and William Van Til, along with their graduate students who have had wide influence in curriculum history and the development of the middle school curriculum.

Peabody College of Education, a private educational institution, emerged out of the division of the University of Nashville and was relocated adjacent to Vanderbilt University in 1911. Although Peabody was a segregated school emphasizing education of teachers and school administrators for White students, a limited program of desegregation (carefully selected principals of Black schools from 13 Southern states and the District of Columbia) was initiated in graduate studies in 1954, and the undergraduate program was desegregated in 1964. Peabody merged with Vanderbilt University in 1979.

By the late 1940s, Peabody was widely recognized as a premier program in the South for future college and university professors. In 1929, the Division of Surveys and Field Services was initiated by Caswell who came to Peabody from Teachers College, Columbia University. Survey research was a design for inquiry and evaluation of school resources and curriculum to support the professionalization of school leadership and modernize curriculum planning and instructional delivery. Over two decades, 47 state and city surveys were completed throughout the South. Caswell remained at Peabody until 1938 and coauthored with Doak Campbell what is often referred to as the first synoptic curriculum text, *Curriculum Development*, in 1935, followed by *Readings in Curriculum Development*, a collection of articles representative of contemporary curriculum concerns. Henry Harap, who had established his reputation for his

promotion of consumer education curriculum and was a principal in the founding of the John Dewey Society, then assumed direction of Peabody's Surveys and Field Services division.

Influence on curriculum scholarship reemerged in the 1950s with Drummond and Van Til joining the Peabody faculty. Drummond collaborated with John Goodlad in authoring a work on educational leadership for building principals in elementary schools in 1956, a practitioner's guide for effective leadership of staff, curriculum planning, and program development. Drummond's scholarship shifted to the development of a popular geography series. *Journeys Through Many Lands*, *Journeys Through the Americas*, and *Our World Today* were widely adopted for use in elementary and junior high schools.

Van Til came to Peabody in 1951 while the institution and then the city of Nashville struggled with racial desegregation. Before his appointment as chair of the Division of Teaching and Curriculum Development, Van Til had been director of Learning Materials at the Bureau for Intercultural Education and professor at the University of Illinois. A recognized advocate of democracy as a key purpose of education and activist for progressive reform, Van Til remained as chair until 1957. As a member of the executive board of the John Dewey Society, Van Til promoted support for implementation of democratic schooling and open consideration of controversial social issues in school curricula. Van Til was directly involved in efforts to advance the *Brown* decree in Nashville public schools.

Harold R. Benjamin joined the faculty as chair of educational foundations in 1951 for a 7-year tenure. Benjamin and Van Til, along with Willard Goslin in school administration and Nicholas Hobbs as leader in psychology, became known on campus as "The Four Horsemen" of Peabody. William H. Alexander received his MA at Peabody in the late 1930s and followed Caswell to Teachers College. After serving in the Navy and in school administration, Alexander returned to Peabody in the late 1950s following publication of a widely adopted guide to curriculum development coauthored with J. Galen Saylor.

Scholars who graduated from Peabody in the 1950s later contributed to curriculum history and practice. O. L. Davis has developed a substantial

body of scholarship on curriculum history at the University of Texas, and John Lounsbury attained prominence for his work in the middle school curriculum as editor of the *Middle School Journal* from 1976 to 1990 and publications editor of the National Middle School Association.

## PEDAGOGICS

---

*Pedagogics* is the systematic, scientific study of the educational process. Unlike *pedagogy*, which retains an emphasis on the humanistic disciplines within the teaching profession, pedagogics almost always refers to the study of teaching and education from the perspective of empirical science. The term is not frequently used in the United States, but it is commonly found in South Africa, Germany, and a few other European countries. Whereas *pedagogy* implies the practice of teaching, texts on pedagogics stress the analysis of educational phenomena with the goal of understanding education from the perspective of an objective observer.

Beginning in the early 20th century, researchers who preferred pedagogics to pedagogy (or education) sought to establish pedagogics as a science distinct from all other fields. In this respect, pedagogics developed similarly to the field of economics, which sought to distinguish itself from politics and ethics. Before this time, politics, ethics, and economics were inseparable. The most significant book published in the United States on pedagogics was Francis Wayland Parker's *Talks on Pedagogics: An Outline of the Theory of Concentration*,

published in 1937. Despite the success of this one book, however, pedagogics never really took off in the United States (nor did pedagogy). Educational researchers in newly established U.S. research universities preferred the term *education* to refer to the kind of work that was being done under the name of pedagogics in Germany and other European countries.

Where it did develop mostly outside of the United States, however, the new science of pedagogics sought to establish its own area of expertise developed by pedagogicians, or experts in the science of pedagogics. Distinguishing itself from the practice of pedagogy, the field of pedagogics grew alongside the new specialization of analytic philosophy. Experts in pedagogics began to explain social phenomena using the methods of analytical philosophers, but they chose to concentrate on their own areas of expertise found within schools, families, and other educational situations. One text by three South African scholars of pedagogics—J. L. du Plooy, G. A. J. Griessel, and M. O. Oberholzer—describes the field as a child of philosophy, but then argues that pedagogics has become an independent science in its own right. These authors go on to explain that pedagogics, as a special type of science, exists to produce knowledge that is verifiable, supplemented by the findings of other scientists, rationally or intellectually obtained, accounted for in a methodical way, generally accepted as being valid, communicable and intelligible, and which may be applied in everyday life by men and women who engage in pedagogical acts. In another text, Griessel describes pedagogics as a field that should inquire into the universal and enduring aspects of education.

The goals of modern social science lay at the heart of pedagogics. The relationship between theory and practice within pedagogics is similar to the relationship between theory and practice in economics. Economists describe how money flows from one area of society to another, but they only rarely venture into the realm of telling practitioners what to do with their money. Similarly, pedagogicians work to explain how learning takes place within various educational settings, but, being scientists, their role is not to provide guidance for teachers and parents about how they should educate their children. Practitioners may use the descriptions that pedagogicians produce,

but the ends toward which they use these descriptions are to be determined entirely by practitioners. The job of pedagogicians is only to explain how the learning mechanism works.

In the United States, much of what takes place under the name of pedagogics can be found in departments of educational psychology. Educational psychologists, like pedagogicians, describe the process of learning with the goal of establishing a “knowledge base” that explains how people learn. These attempts to establish pedagogics (or learning) as a separate field of research, however, have been met with frequent controversy. The most common criticism has been that a science of pedagogics (or learning) cannot (and should not) be divorced from curriculum.

## PEDAGOGY

---

Stated simply, *pedagogy* is the art of teaching. However, it is important to explore what “art of” really means to recognize the vitality and complexity of the term. When educational practices ascend to the designation of “art,” it means those involved are making intentional decisions based on a set of beliefs. Further, as in any performing art, there is a desire to refine one’s efforts—to achieve an ideal of perfection. To that end, the artist engaged in art as well as the teacher engaged in pedagogy become acutely aware of the nuances, flows, and tensions within their work so they can move closer to their images of the ideal. Thus,

consciousness, intentionality, refinement, and belief are critical elements within any pedagogy.

### Pedagogy Versus Instruction

Although pedagogy requires some larger ideal or set of beliefs to give it life and form, instruction does not. Instruction can occur with no set of larger beliefs or with no larger ideal in mind. It is a technical process that can be applied relatively context-free. For this reason, *instruction* is often used as a primary mechanism for thinking and planning about the enactment of a number of the reform models used in recent years. Further, the term *instructional leader* is often used to refer to principals and the ways they work with teachers without any specific image regarding the larger values, aims, and beliefs of education. Instead, the instructional leader is often seen as one who manages instruction for the sake of efficiency and, consequently, higher test scores. By the same token, much has been written in recent years about best practices, which are instructional techniques teachers can do (relatively context free) to bring about higher achievement as measured through standardized tests. This trajectory of privileging images of instruction over pedagogy is supported by policies and practices that make “achievement” the sole aim of schools and, subsequently, standardized tests as the primary if not sole measure of that aim.

In contrast, pedagogy does not exist outside of larger ideals or beliefs. Larger aims animate pedagogy and give purpose to the efforts of the teacher. For example, Paulo Freire developed a specific way to teach illiterate Brazilians who lived in oppressed villages during the 1960s. His work included entering the villages to learn about the people and their lives. It also involved listening to the villagers to understand what words were important to them. Freire and those who worked with him would use the language and experiences of the villagers to develop generative themes for literacy lessons. In these lessons, they would teach the villagers to see how they had been oppressed and how the power of literacy could help them overcome their oppression. Freire’s work with the oppressed and illiterate Brazilians was not merely a set of effective instructional techniques. It was, instead, work animated by strong convictions about justice and empowerment. Freire believed

that political and social systems had relegated many people into the role of objects—seemingly powerless to change their circumstances. He fought to empower these individuals so they could be subjects with control over their own lives and the well-being of their communities. Further, Freire believed this shift was possible only through a heightened sense of critical consciousness. These convictions about justice, power, and critical consciousness permeated Freire’s pedagogy of and for the oppressed he taught in Brazil.

### Examples of Pedagogy

Critical pedagogy, as seen in the work of Freire, is one example of a common ideal from which individuals think about, plan for, and enact their work in classrooms. When teachers are deeply concerned about social justice and agency, then they become more aware of how they work toward justice in their own classrooms. They are more mindful of the political nature of the world, the systemic social functions and structures that perpetuate injustice, and the ways in which those in power can influence what counts as knowledge, what priorities a community should strive to achieve, and even how individuals define themselves. Because these issues influence so much of how they see the world, teachers engaging in critical pedagogy teach in a way that is responsive to these issues and the potential for education to make changes in the world. These teachers strive to be just in their classrooms, and they work to empower their students to seek justice now and in the future.

Culturally relevant pedagogy addresses the need to be responsive to cultural differences within the classroom. Teachers who view their work through lenses of critical race theory or multiculturalism recognize the White, Eurocentric nature of much of what happens in schools. Further, they see how some culturally diverse students do not achieve as well in these settings. Teachers operating from this perspective strive to use the experiences and frames of references of culturally diverse students to make schooling more relevant and affirming. By doing so, they work to raise the level of achievement of the culturally diverse students.

Another example, feminist pedagogy, is rooted in the belief that human experiences are gendered and therefore shaped by one’s gender. Teachers

operating from a feminist lens work to challenge and change patriarchal structures and policies within schools. Teachers engaged in feminist pedagogy work to review what is possible both within the classroom and within the world when gender-based ways of being and ways of knowing are deconstructed. Their aim within their classrooms is to help students transcend gendered and limiting notions of themselves and their world.

## PERFORMANCE ASSESSMENT

---

*Performance assessment*, also known as alternative assessment, is a method of educational evaluation based on the measurement of an individual’s proficiency at executing various complex tasks, such as writing an essay, following a lab protocol, or solving multistep problems. Equal attention is paid to the how and why answers or solutions are reached for the results. By attending to the learner’s practices, educators can identify and correct flaws in action and reasoning. In this way, it is argued, assessments can more effectively evaluate and remediate learning.

Practitioners of performance assessment hold that their evaluation methods provide a wider array of skills and information for measurement and analysis. They add that its residual effects are improved lesson planning and teaching practices. Advocates further argue that their practices are

more flexible at evaluating, and adjusting the processes and strategies students use in problem solving. These practitioners explain that standardized tests simply evaluate the collection of static information without determining the learner's capacity to employ that information in answering more complex questions. Performance assessment, it is offered, provide instructors with greater insight into an individual's thinking processes.

As a means of improving teaching practices, performance assessment calls on teachers to attend to the methods and procedures of learning, to help students integrate knowledge and skills in creating a personal toolkit for problem solving and integrating concepts and ideas. This calls for educators to aggressively facilitate learners' need for sources, tools, and time devoted to their problems, along with a meaningful curriculum, reflecting the real-life problems. Such dramatic changes will require many to restructure curriculum, modify testing methods and timetables, and redefine workloads and job descriptions of teachers and administrators.

Performance assessment calls for greater interaction among teachers and students and a more intensive observation of a learner's actions, reasoning, and development. Classrooms will need to see better cooperation and more collaborative projects. Learning will need to be more hands-on and interactive as learners construct knowledge and practices. Educators will need to give greater attention, to individual students and to the methods and procedures that they themselves use as they assist learners in choreographing and refining their actions and competencies.

Performance assessment is a topic of growing importance in curriculum studies because it presents an alternative to current standardized testing regimens. Critics of present evaluation methods, question their effectiveness in measuring real learning, the validity of what is being tested, and how well these assessments inform and remediate student's practices. The full implementation of performance assessment will call for changes in how lessons and skills are presented and how facts, theories, and concepts are integrated into learning. Educators have long searched for evaluation tools that are fair, accurate, and provide meaningful and timely data that informs students and instructors alike. Performance assessment offers new and

promising methods for evaluation as well as unique sources for measurement. Along with this, it demands a greater investment of time, effort, and resources, factors hindering its broader implementation by school districts.

Critics of standardized testing systems point to serious problems and consequences created by test-driven curriculum programs, citing problems such as time limits on exams, limited response choices, and answers that are short, meaningless, and decontextualized. No Child Left Behind funding, based on standardized assessment programs, has the consequence of fostering bad practices, disrupting class and study time to teach to the tests that will evaluate their performance. This may lead some schools that are most in need of time for studies and thoughtful and expansive learning to cede that time to repetition, drilling, and prepackaged lessons.

Supporters of performance assessment have identified characteristics that are most exemplary of effective measurement procedures that support learning. Many of these features will be a part of any comprehensive authentic assessment protocol.

- Assessment should be based on real-life, practical tasks involving communication skills, step-by-step technical expertise, or the processes of solving complex mathematical problems.
- Data should inform assessors of the mastery of information and of the potential for its application.
- Problems and challenges should engage higher order thinking and allow learners to experiment with complex problem solving skills, and offer the opportunity to hone and refine skills and develop proficiency.
- Projects calling for critical and creative thinking, problem solving using a variety of reasoning schemes, and writing assignments asking open-ended questions exercise the imagination and promote the development of communication skills.
- Lessons and projects should strive to widen perspectives, evoke a greater range of responses, and stimulate an appetite for inquiry.

Advocates of performance assessment promote learning using principles of constructivist and experiential learning, multitasked projects, procedures,

and challenges that promote exploration and experimentation. Storage systems and schemes for artifactual collections (i.e., portfolios, electronic storage) provide learners with progressive evidence of their mastery of skills and create a source for reflection and further development. Open-ended questions and questions calling for essay answers and paragraph responses promote the learner's reasoning and communication skills. Projects and exhibits demonstrate a learner's ability to organize and execute longitudinal plans and incorporate disciplines in complex processes and skills to achieve a goal.

Questions still exist concerning the consequences of performance assessment, issues of fairness, transfer and generalizability, meaningfulness, cost, and efficacy. Many of these issues will be explored as performance assessment is further implemented and as standardized testing incorporates many of its elements and philosophies into its test practices. The hope is that performance assessment can resolve these concerns and continue to contribute and change the ways educators teach and assess.

describing that culture and the treatment of one's own story as an expression of a culture) with post-modern performance theory. For curriculum studies, performance ethnography offers a specific orientation toward doing curriculum research on both curriculum artifacts and curriculum practices (designing, developing, etc.) in which the researcher is profoundly implicated in the "outcomes" of the research.

Performance theory for social scientists comes out of the work of theater scholars such as Richard Schechner and is extrapolated to everyday life. Performance theory points to "performance" in two ways. There is "performativity" in which the actual process of undergoing our lives is a performance, similar to the work done by Erving Goffman analogizing social interactions to theater. "Performativity" is the present tense of social action as we perform ourselves, presenting aspects of ourselves selectively with both intention and unintention. Our performance is always mediated through culture and politics. There is never an innocent, pure self that is free of culture. Auto-ethnography's contribution to performance ethnography lies with that premise, building a research practice around narratives of self that are linked to the cultural context in which the self is becoming a self. Linked to this is "performance," a finished product of performativity, completed and ended. "Performance" references the looking back at performativity as memory. When people engage in stories about the past they are engaging in describing, discussing, and locating meaning through examining performances of self. Both performativity and performance are performative features of how people actually live their lives. We are always performing our lives rather than presenting them innocently and purely.

Performance ethnography presents a view of research in which the researcher is deeply implicated in the final expression of the research (the conclusions made, the articles, books, presentations of all sorts shared with others) *and* in the actual unfolding of the research. This "actual unfolding" is performativity itself. In performance ethnography, the researcher recognizes the performative character of asking research questions, setting up research opportunities, seeking out informants, actually gathering information from the field, thinking through and analyzing what is

---

## PERFORMANCE ETHNOGRAPHY

---

*Performance ethnography* is a melding of ethnographic and auto-ethnographic practices (the immersion in another culture for purposes of

“learned,” and organizing all of that for sharing with others. In the performative situation, there are no firm conclusions because the act of interpretation for the purposes of organizing and carrying out research are always ongoing, evolving performances of what is occurring. Through the auto-ethnographic character of performance ethnography, the researcher recognizes that he or she is performing culture through his or her own specific cultural or social location. The researcher often will tell performance stories of his or her experiences within the setting as a way into the situation because the researcher already recognizes that he or she is seeing through his or her personal sociocultural resources that preinterpret the scene. Performance ethnography draws from standpoint theory in this regard. Performance ethnography rejects the standard Western modern notions of distanced research objectivity in favor of this deep presence of the self of the researcher. In doing so, performance ethnographers see a need to present the actual research in new, aesthetic forms that are more capable of both revealing the performativity of the researcher and of engaging the recipient of the research in ways that implicate the receiver (so that he or she also experiences the performativity of encountering the research). For curriculum studies scholars, performance ethnography presents possibilities of encountering curriculum artifacts and practices through the self as the conscious tool of understanding. The “self” is seen as an experienter and interpreter of culture through the personal and immediate (performativity). Thus, if the curriculum studies scholar is studying a curriculum design practice or studying curricula as experienced by those involved in living the curriculum design, he or she will study his or her responses (as cultural) to the situation and how the situation situates the researcher, rather than studying the practice as an outside, distanced, disinterested eye observing what others are doing. Performance ethnography, with the willingness of its practitioners to use alternative forms of research and research presentation, offers curriculum studies scholars new ways of performing and presenting this research (forms such as poetry, narratives, theater work, visual art, dance and performance art, to name a few).

Performance ethnography offers a further characteristic important for curriculum studies. Norman Denzin, a leading developer of the notion

of “performance ethnography,” aligns performance ethnography with a social justice framework. He argues for the immediacy of recognizing that we are performing life rather than simply fulfilling life’s mandates. This recognition affords the possibility of seeing our actions from within a personally recognized, realized sociohistorical-cultural context that can bring us up short so that we may fruitfully confront our own implication in injustice. In so doing, he argues that we will be motivated to contribute to the ongoing struggle to make a better, more just world. Thus, performance ethnography can contribute to the larger critical social curriculum studies project as described by such social theorists and curriculum studies scholars as Henry Giroux, Peter MacLaren, and Gloria Ladsen-Billings.

## PERFORMATIVITY

---

The theory of performativity is centrally important to curriculum theorists who examine relationships among power, identity, and culture from a poststructural perspective. Performativity is based on an understanding of human reality as discursive, as produced not through a natural truth but through the constant repetition of discourses that *perform* our understandings of what is true or real. From this perspective, identities are not natural attributes; rather, they are the result of mundane practices of social norms and represent compulsory social practices.

Performativity theory is most closely related to the work of feminist theorist Judith Butler. Butler draws from J. L. Austen's and John Searles's work on speech acts and from Michel Foucault's understanding of truth as a discursive production of power and knowledge. Butler explores the constitution of naturalized gender, sex, sexuality, and race through reiterative performances of normative behaviors, speech, and gestures. This repetition creates the appearance of stable and taken-for-granted ways of being in relation to recognized identity markers for the social audience and for the performer. Performances of identity inscribe the body with physical stylizations and desires that are mistaken as the individual truth of each person; while they are experienced as real by individuals, they reference not natural reality but the citational nature of reality.

Identity is performed with both pleasure and fear. Identity functions to provide a sense of meaning and belonging through the structuring of desire and gratification in relation to identity norms. Identity defines the behaviors, beliefs, and interests that are privileged as normal within a given identity group. In sharing these with others, individuals can create and solidify social bonds that provide feelings of warmth, belonging, meaning, and satisfaction. At the same time, along with the pleasures of identity, there is always a threat. Those whose identity performances are outside the acceptable range can face sanction and punishment. The force of social sanction enacted by peers, family, friends, strangers, and professionals (e.g., teachers, specialists, counselors, lawyers, doctors) threatens discipline. Identifying and punishing those outside the norm bestows the social privilege that comes with being perceived as normal to those who toe the line and communicates what happens to those who step over the line.

Although this description of performativity suggests a highly determined perspective, theorists working from this perspective point out that there is no single set of norms for any identity. Rather, there is a range of practices that are understood to mark a given identity. Further, individuals express multiple identities and the norms of these identities can come into conflict. For example, the contested meanings of "woman" became clear when White U.S. feminists of the 1970s and 1980s were criticized for putting forth definitions of gender that

failed to recognize the raced and classed interests within their universalized claims. Individuals can likewise experience conflicts within the demands and expectations of their self-identifications. Because norms gain authority through the establishment of the nonnormative, norms inevitably generate their own resistances. Because identities are not natural but produced, they require constant performative reiteration to maintain their authoritative position. Therefore, the insistent performance of identifications, behaviors, and desires that violate the norm demonstrates that they are not natural and opens up the possibility of a more inclusive space.

Curriculum theorists working from a performativity perspective may examine curricular texts or practices or classroom interactions for performances of speech and behavior that reiterate or challenge social norms. Examples of this work include examinations of the discursive production, regulation, and rearticulations of gender, race, and sexuality in the performances and disciplining of teacher and student identity in schooling.

---

## PERSONAL PRACTICAL KNOWLEDGE RESEARCH

---

Research studies in *personal practical knowledge* have had a significant impact on scholarship in curriculum studies and how educators think through problems pertaining to teaching and

learning. Personal practical knowledge is often characterized as a form of situated knowledge and associated with feminist standpoint theory. It is generally understood to be shaped and influenced (but not solely determined by) one's social position, emotional life, politics, institutional demands, conscious and unconscious desires, tastes, and aesthetics. Personal practical knowledge is also described as implicit, taken-for-granted, fluid, and tacit. The term *personal practical knowledge* has been used in curriculum studies to account for what has been termed the *tacit knowledge* that influences teachers' practical action in the classroom. Studies that use personal practical knowledge as a unit of analysis have explored how experienced teachers make decisions about teaching in the classroom based on practical experiences cultivated during their careers.

The use of the term *tacit* suggests that practical knowledge is implicit and not available to consciousness. It also summons the concept of *tacit knowing* developed by the philosopher and scientist Michael Polanyi who wrote about a process of knowing that is apparently inexplicable. Relevant to the idea that personal practical knowledge is often tacit is the fact that such knowledge is believed to consist of habits, cultural practices, beliefs, and rituals that are so taken for granted in a person's daily life that they remain opaque and, consequently, are not passed on through explicit instructions or in formal settings. Tacit knowledge is understood as involving skills and technique, a sense of timing and a repertoire of methods, but following Polyani, remains unspoken.

Personal practical knowledge has long been recognized as having broad relevance for research in teacher education, autobiographical studies, curriculum theory, and professional development for teachers and administrators. One can trace the discourses of personal practical knowledge to studies interested in "how teachers think," as well as "teacher lore," and scholarship that has focused on studying teachers' lives. Understood at its most foundational level, personal practical knowledge is constituted by a set of discourses that have worked to engage the productive tension between theory and practice, educational scholarship and classroom practice, and, to illuminate the value of inquiry in education that involves practitioners and scholars in discovering modes of research that

serves students, teachers, and communities by recognizing the vital role that social context plays in educational experience. Implicit in the study of personal practical knowledge is the work of reflecting and elaborating on one's educational and pedagogical experiences for the purpose of provoking deeper insights and understandings into education in and out of school.

Research in curriculum studies that understands personal practical knowledge as tacit is vulnerable to critique from a range of disciplinary fields, particularly given that educators are often consciously aware of the practical theories they use and are articulate about these theories. Research critical of the notion that personal practical knowledge is tacit works toward elaborating the complex conceptual structures, metaphors, and visions that educators use to justify why they act as they do in the classroom and for choosing curriculum materials, teaching activities and classroom arrangements to effectively engage their students. They refer to the principles and propositions that underlie and guide teachers' approximations, decisions, and actions as "practical theories of action," which might be understood as a more refined articulation of earlier understandings of personal practical knowledge as tacit.

A related but distinct construct of personal practical knowledge is *pedagogical content knowledge*. This construct refers to the theories of action taken by teachers in classrooms as "practical theories." These theories are understood in contrast to educational theory, which select scholars in teacher education have found many teachers to have little faith in, and those theories developed by teachers through their practices. Pedagogical content knowledge is not understood as tacit, nor is it located solely in the individual teacher; however, like personal practical knowledge, this knowledge is situated in the work of practice, is derived from practice, and informs practice as a social and institutional project that is at once personal and social.

Personal practical knowledge is also associated with "pedagogical reasoning and action," which refers to the modes of reasoning that teachers engage in as they conceptualize content knowledge and reorganize it so that material can be effectively communicated to students.

It has been argued that scholarship drawing on concepts of personal practical knowledge works to

dismantle the hierarchical expert/client relationship or vertical power structure often present in university-school research projects and that, as noted earlier, often generates suspicion among teachers and holds fast to misconceptions about the distinctions between theory and practice. However, critics argue that the notion of personal practical knowledge fails to address the institutional and social elements that affect pedagogical practices and locates knowledge about teaching in the hands and heads of individual teachers. This approach to understanding how knowledge is generated and put to work has been understood as isolating teachers within the limits of their personal, practical understandings and setting them apart, not only from one another, but from engaging with institutional structures that create and sustain inequities and undermine the professional authority of teachers. Concern has been expressed that personal practical knowledge is inclined to be falsely reassuring and therapeutic and is too often devoid of social critique and awareness of the workings of ideology.

## PHENOMENOLOGICAL RESEARCH

---

Phenomenology is a project of abstemious reflection on the lived experience of human existence—abstemious, in the sense that reflecting on experience must, as much as possible, abstain

from theoretical, prejudicial, and suppositional intoxications. But, phenomenology is also a project that is driven by fascination: being swept up in a spell of wonder, a fascination with meaning. The phenomenologist directs the gaze toward the regions where meaning originates, wells up, percolates through the porous membranes of past sedimentations—then infuses, permeates, infects, touches, stirs us, and exercises a formative affect.

Within the broad field of curriculum studies, phenomenology is a form of inquiry that historically has induced several distinct perspectival interests, purposes, and practices. The perspectives are briefly outlined in this entry in terms of critical onto-theology, extended imaginary, and phenomenological research as interpretive method. Onto-theology refers to the larger metaphysical and philosophical assumptions about what is real, meaningful, relevant, and consequential for the way we live and understand the nature of education, pedagogy, knowledge, ethics, childhood, teaching, learning, and so forth. The extended imaginary is the cultivating of insights about fundamental curriculum notions and concerns through the mediation of rich and inspiring phenomenological literature. Descriptive/interpretive method provides access to phenomenological research approaches and ways of thinking, inquiring, and reflecting on topics of curricular and pedagogical interest.

In engaging phenomenological research with curriculum and pedagogy, one needs to make some distinctions between phenomenological literature that historically is included in curriculum studies and literature that identifies itself with the fields of philosophy of education, educational psychology, counseling, and administration. Some scholars such as Maxine Greene have straddled the disciplines of philosophy of education and curriculum studies; others, such as Donald Vandenberg and Thomas Greenfield have published and situated themselves more strongly within the fields of philosophy or administration. This entry is limited more closely to the literature that has primarily engaged with curriculum and pedagogy.

### Phenomenological Research as Critical Onto-Theology

*Onto-theology* is a term used by Immanuel Kant and especially Martin Heidegger to describe the

metaphysical undercurrents of Western culture that condition the technological nature of all human forms of inquiry. Dwayne Huebner and Maxine Greene were forerunners among curriculum scholars who turned to the thought of Heidegger, Jean-Paul Sartre, Maurice Merleau-Ponty, Karl Jaspers, Albert Camus, and Hannah Arendt as intellectual sources for expressing critical concerns with the pervasiveness of positivism, instrumentalism, and technologism in the field of curriculum and teaching. From an emerging phenomenological perspective, Huebner and Greene already warned in the 1960s against the damaging dominance of technological, instrumental, and calculative thought in the field of curriculum studies. In subsequent years, Greene criticized the traditional epistemologies of educational research and the limiting consequences of these epistemologies to the shape of educational thought and pedagogical practices. William Pinar turned to Sartre's *Search for a Method* to find existentially sensitive directions for curriculum thought. And Max van Manen explored how different ways of knowing are related to ways of being practical.

The onto-theological roots feeding the technologizing of professional knowledge have not diminished. On the contrary, the influence of communication and information technologies and market economies in the administration of schools and educational systems may have pushed the technological onto-theology even more deeply into the metaphysical sensibilities of Western cultures. There is a certain irony in the fact that even the increasing popularity of qualitative inquiry in curriculum studies has not prevented professional practice becoming cemented ever more firmly into preoccupations with calculative policies and technological solutions regarding the productivity of learning outcomes, the accountability of standards of practice, the measurement of educational effectiveness in terms of school ranking, the codification of ethics governing programs of research and teaching, and so forth.

### Phenomenological Research as Extended Imaginary

The imaginary is a notion that Sartre used to describe extended reflections, meditations, and examinations from the point of view of the work and thoughts of Edmund Husserl, Martin Heidegger,

Henri Bergson, and other early phenomenological scholars. In the field of curriculum studies too, phenomenology has been used as a resource for rethinking and reconceptualizing the meaning of curricular and pedagogical concepts and processes.

An early example of the extended imaginary in curriculum is Huebner's "Curriculum as Concern for Man's Temporality" wherein he questions the meaning and centrality of the concept of learning and reflects on Heidegger's *Being and Time* to rethink teaching as being and curriculum as environmental design. In *Existential Encounters for Teachers*, Greene advances a kind of phenomenology of literature to teaching. In her various writings, she shows how fictional literature and poetry make it possible for the reader to "see" aspects of human experience that cannot be stated discursively, cannot be translated into fact, or assimilated into a body of knowledge. And yet, these forms of human understanding cannot be achieved by the epistemologies of science and research as promoted by mainstream curriculum scholars. Ted Aoki loosens the gnostic nature of curriculum by drawing distinctions between curriculum as planned and curriculum as lived, the goals and the intentionalities of teaching. And van Manen shows how phenomenological pedagogy is primarily an ethical orientation to the lived experience of the child or student, and how an epistemology of practice presupposes an ontology of thoughtfulness and tact of teaching.

In addition to curriculum scholars who turned to phenomenology for gaining insights into curriculum concerns and concepts, there are precursors among curriculum scholars whose works arouse the sensitivities that a phenomenological approach requires. An outstanding example is John Dewey's *Experience and Education*, wherein the eminent philosopher argues for the need for a reflective understanding of the meaning of student experience. Another precursor to the phenomenological interest is Philip Jackson's inspiring study of *Life in Classrooms*, wherein he engages with the complexities and experiential concreteness of mundane details of classroom life and living.

### Phenomenology as a Tradition of Traditions

Phenomenology consists of a complex web of traditions rooted in continental philosophy and now

globally diversified across all major human science and professional disciplines. Transcendental phenomenology is the name of the tradition that begins with Husserl. Husserlian phenomenological research proceeds through transcendental reflection as practiced through the eidetic reduction (bracketing) or epoché. In the transcendental reduction, the researcher withdraws from the natural attitude of the taken-for-grantedness of the everyday world and of objective science. Husserl stresses that the phenomena (persons, things, objects, events, ideas, etc.) of which we are conscious are not simply retrievably *in* consciousness (as *in* a box); rather, they are *constituted* as being what they are for us and as what they mean for us. Husserl's writings are often bypassed by contemporary researchers in education, in the mistaken belief that they are now irrelevant. An influential adaptation of the Husserlian approach that explicates and emphasizes the methodological significance of the eidetic reduction for practical inquiry is found in works of the psychologists Amadeo Giorgi and Clark Moustakas. A curricular example of this influence is Carol Thomson's article on phenomenology in teacher education contexts.

Ontological phenomenology inquires into the nature of human existence or modes-of-being in the world. Heidegger distanced himself from the Husserlian preoccupation with eidetic description, in favor of an ontological and interpretive perspective. Heidegger points out that human existence (*Dasein*) is always already embedded in a world of meanings. Things are not primarily phenomena that are constituted in consciousness; rather, we encounter them immediately in the world where we use them. For Heidegger, phenomenology is the study of what shows itself in the unique manner in which it shows itself to us. Every mode of being (such as the mode of being a student, a teacher, a reader, a scientist, a parent) is always simultaneously a way of understanding the world. These modes of being in the world need to be interpreted, as in David Denton's early reflections of the being of teaching and more recently Gloria Dall'Alba's ontological consideration of becoming and being a teacher.

Hans-Georg Gadamer continues the development of a hermeneutic phenomenology, especially in his famous text, *Truth and Method*. Heidegger and Gadamer (like Husserl or any other phenomenological philosopher) do not offer

a set of determined research methods for conducting hermeneutic phenomenological inquiry, but their works are inspiring examples both in their form and content. In *Truth and Method*, Gadamer carefully explores the hermeneutic role of language, the nature of questioning, the phenomenology of human conversation, and the significance of prejudice, historicity, and tradition in the project of human understanding. All these topics have relevance for curriculum inquiry, typified in the writings of curriculum theorists such as David Jardine.

Existential phenomenology is famously presented in the works of Sartre and Merleau-Ponty. The relevance of existential phenomenology for education lies in its focus on the world of lived experience and on embodied, linguistic, gendered, and intersubjective dimensions of human existence. In his preface to the *Phenomenology of Perception*, Merleau-Ponty suggests that phenomenology begins in awakening and describing the basic experience of the world. Sartre points out that lived experience cannot easily be accessed through narrative experiential accounts because retrospective descriptions turn unreflected experience into reflected (and thus distorted) accounts. Similarly, the Husserlian reduction always objectifies the experiential subjectivities that it tries to capture and describe. Sartre argues that the challenge of phenomenological inquiry is that it must remain attentive to unreflected experience as we live it in our daily lives by joining in a sort of conspiracy with it. This conspiratorial joining requires a type of intentionality and evocative sensitivity that remains attuned to the prereflectivity of lived experience as in van Manen's phenomenological pedagogy of *The Tact of Teaching*.

We can speak of a radical linguistic phenomenology in the poststructuralist writings of Jacques Derrida and his French colleagues such as Julia Kristeva and Hélène Cixous. Derrida aims to show that meaning is always primarily linguistic. Meaning resides in language and the text rather than in the subject. In contrast to Husserl's search for an indubitable ground of human understanding in the cogito, Derrida points out the essentially unstable and undecidable character of the nature of signs and meaning. Through the method of deconstruction, Derrida aims to demonstrate, not the invariance (essence) of human phenomena but the

essential variance, the *différance* that destabilizes all meaningful distinctions and discernable identities. Examples of the deconstructionist approach to curriculum may be found in *Understanding Curriculum as Phenomenological and Deconstructed Text*, edited by William Pinar and William Reynolds.

Ethical phenomenology is especially associated with the original and influential work of Emmanuel Levinas, who intended to radicalize the thinking of Husserl and Heidegger into a phenomenology of otherness. For a truly profound understanding of the human reality, one must not (only) inquire into the meanings that are constituted in consciousness (self) or that inhere in being (presence), but for the meaning of what is otherwise than being, alterity, or difference. Levinas finds the phenomenological power of this question in the encounter with the face of the other who addresses us. In the vulnerability of the face of the other, we experience an appeal: We are being called and even taken “hostage.” Our response to the vulnerability of the other is experienced as a responsibility. This is an ethical experience, an ethical phenomenology. The work of Levinas has particular relevance to the normative project of pedagogy as well as some contemporary curriculum discourses. For example, drawing on Levinas, Paul Standish emphasizes the invocational over the representational language of curriculum.

### Phenomenological Research as Human Science

Phenomenology is a philosophical approach to inquiry that is guided by methods such as the transcendental reduction, ontological analysis, hermeneutic interpretation, existential reflection, conspiratorial attentiveness, deconstructive analysis, or ethical responsiveness. As a professional discipline in curriculum and pedagogy, phenomenology is aided by human science procedures and techniques such as experiential interviewing, experience-sensitive observation, thematic analysis, and so forth.

However, phenomenology is not just a method that one can employ like a set of procedures. It is also an attitude that relies on the perceptiveness, creative insight, interpretive sensitivity, scholarship, and writing competence of the researcher. The phenomenological attitude constitutes a fascination with the uniqueness, the particularity of an

experience or phenomenon. When I am in love and I reflect on the meaning and significance of this love, then I am compelled not by abstractions but by the concreteness of my experiences: the sweet taste of that last kiss this morning, the tenderness I feel when I look in my love’s face, the longing I experience when reading the love letter, the desire I experience to be the object of my lover’s desire, the arousal of voluptuousness. Thus, a phenomenology of love is not primarily pursued through a theoretical discourse or a conceptual analysis of the notion of love. It is pursued through attempts to awaken the experience as we live it, and make contact—through concrete examples and reflection—with the living sensibility of its uniqueness.

Phenomenological research is oriented to the lifeworld as we immediately experience it—prereflectively, rather than as we conceptualize, theorize, categorize, or reflect on it. It is the study of lived or experiential meaning and attempts to describe and interpret these meanings in the ways that they emerge and are shaped by consciousness, language, our cognitive and noncognitive sensibilities, the ontics of meaning, and our personal, social, and cultural preunderstandings. Phenomenology can be adopted to explore the unique meanings of any educational experience or phenomenon.

Phenomenological research within the spheres of curriculum and pedagogy may address questions such as, What is the student experience of recognition, disappointment, motivation, examination, and so on? What is the experience of epistolary writing? How is a class conversation different from discussion, argument, or debate? How do students and teachers experience digital media technologies in the classroom? How is the body experienced in online teaching and learning? In a broad sense, any curricular or pedagogical experience may become the focus of phenomenological research.

The practical significance of a phenomenological research should not be sought in instrumental action, efficiency, or technical efficacy. Rather, the significance of a phenomenology of practice lies in its formative power, issuing from the sensitizing effects and affects of phenomenological reflections. Phenomenological understanding inheres in the sense and sensuality of our embodied being and practical actions, in encounters with others, in the ways that our bodies are responsive to the things of

our world, and to the situations and relations in which we find ourselves. Phenomenology of practice is an ethical corrective of the technological and calculative modalities of contemporary life. It finds its source and impetus in phenomenological research, and of phenomenological reading and writing that open up possibilities for creating formative relations between being and acting, self and other, interiorities and exteriorities, between who we are and how we act.

sounds of spoken English to individual letters and groups of letters. A variety of different approaches to decoding exist that are called "phonics," but these methods are not interchangeable. Although used in most primary grade reading programs, how and if phonics should be used has been and remains a sometimes-controversial topic. Some curriculum theorists would term phonics a *social efficiency ideology*, focusing as it does on achieving a social good (i.e., improved decoding skills), through instruction that is often programmed and standardized. This entry examines the theoretical underpinnings of phonics, the historical controversy with advocates of other approaches, some of the different phonics approaches used in the schools, and its lasting influence today.

Phonics is predicated on the *alphabetic principle*, where letters, either singly or in combination, are used to represent speech sounds, which are also known as *phonemes*. Phonics is relatively straightforward in Romance languages, such as Spanish, because of their nearly one-to-one correspondence between sounds and their representative letter patterns. Phonics in English is more complex, however, because the 40 or more phonemes in the spoken language are represented with only 26 letters. To represent certain distinct sounds, two letters are sometimes fused together to form *digraphs*, such as when "s" and "h" are joined to stand for the sound /sh/. English has absorbed words from other languages, especially Old English, Danish, French, Latin, and Greek, so the same sound can often be spelled in different ways, and identical spellings can represent different sounds. Research suggests that English spelling rules that consider syllable structure, phonetics, and accents are reliable more than 75% of the time.

The complexity and inconsistencies underlying English phonics have generated many criticisms of it as a method of instruction for young children. The controversy related to the value of phonics instruction is not of recent origin, and educators such as Horace Mann criticized the technique as "soul-deadening" more than a century and a half ago. Over the decades, alternative teaching methods have been developed and promoted that emphasize engaging with all aspects of the language rather than phonics' perceived emphasis on part-to-whole. Influential alternatives to a phonics-based approach have included the "look-say" or

---

## PHONICS/READING ISSUES

---

*Phonics* refers to an instructional method whereby children are taught to decode words by linking the

“whole word” methods, popularized by the Dick and Jane basal readers, and the whole language movement of the 1980s. These substitute reading programs had critics of their own. Disagreements about the best practices in literacy instruction have been termed the “reading wars,” with researchers, educators, parents, and others all weighing in on the relative merits of different approaches. The disagreements about the role of phonics have sometimes been emotional, contentious, and bitter. The dispute centers on the question of focus in the early grades: Some favor more emphasis on decoding, whereas others stress the meaning of language. These disputes have sometimes spilled into the political arena, with legislation regarding the teaching of phonics being considered and sometimes passed at the state and federal level, including No Child Left Behind. Proponents of phonics are sometimes painted as favoring a more traditional, authoritarian type of instruction. Although today most reading experts agree that phonics instruction has value, the precise role, and form, of that instruction can vary greatly.

This confusion is exacerbated by the variety of different phonics approaches used today, such as analogy phonics, analytical phonics, embedded phonics, and synthetic phonics. *Analogy phonics* has students analyze phonograms, composed of a vowel and the sounds that follow it, such as -op. Students memorize a bank of phonograms and use the phonograms to analogize unknown words. With *analytical phonics*, children explore sound-symbol correspondences but do not blend sounds together to make words. Children using analytical phonics might be asked to identify common phonemes in a set of words and then explore how the words are alike. *Embedded phonics* is often used in whole language classrooms. Embedded phonics maintains the focus on the literature’s meaning while addressing phonics concepts that students are struggling with or new patterns that may occur in a reading assignment. Finally, *synthetic phonics*, sometimes referred to as *systematic and explicit phonics*, provides explicit direct instruction as to various sound-symbol correspondences, and teaches children how to blend the phonemes learned into words and how to segment words into phonemes. Although these various approaches to phonics instruction each have merits, they often

result in different reading programs, both in appearance and results.

Contemporary curriculum theorists continue to address the role phonics plays in U.S. public schools. *Social meliorists*, for example, who view schools as vehicles for change that can improve the lot of students, are highly critical of phonics. In the social meliorists’ view, phonics instruction too rigidly reinforces differences that are based more on socioeconomic status, class, race, heredity, and other factors than on intelligence. Phonics is seen as focusing too much on achieving predetermined goals that reproduce and reinforce the extant social structure rather than on building on the individual child’s knowledge and background. *Developmentalists*, who concentrate on children’s emotional and behavioral development, are also critical of phonics. Developmentalists question using phonics programs that are based on preconceived notions regarding pacing and the introduction of various letter sounds and blends as these are not built on individual needs. Developmentalists instead advocate for phonics instruction that is differentiated based on a child’s specific requirements, preferring to wait for the teachable moment rather than for adherence to packaged instruction. A third group, those interested in *social efficiency*, accept and indeed advocate for systematic and explicit phonics instruction. Social efficiency educators strive for a curriculum that builds the individual child’s capacity. Phonics, which can be efficiently taught and assessed, is seen as an ideal means of providing results to society.

Phonics-based approaches to reading instruction remain popular, widespread, and controversial in schools. Although growing consensus exists about the necessity of including phonics instruction in the classroom, no such agreement exists about the amount of time devoted to that instruction nor on the form in which it should be delivered. Educators continue to struggle with the appropriate balance of time and instruction devoted to learning how to decode versus that spent interpreting the meaning of language and literature.

## PHYSICAL EDUCATION CURRICULUM

---

Contemporary physical education curriculum today, as it pertains to the consideration of central issues of curriculum studies about what is worthwhile, has come a long way from issues of credibility and data-based studies to issues of what is worthwhile in physical education curriculum.

### Physical Education as an Academic Discipline

In the 1960s, physical education was primarily viewed as a teaching field in higher education, with the exception of one specialization, exercise science, which fueled the drive to be “more academic.” At the time, there were no systematic research programs in place other than some positivist-oriented research. Attempts to create a theoretical structure for the field began at this time.

More changes were on the horizon as well, driven at least in part by the need for academic credibility in higher education and the success of exercise science with its established body of research. The most notable change, following the path of exercise science (increasingly referred to as exercise physiology), was the development of other subdisciplines, such as sport psychology, sport sociology, sport philosophy, biomechanics, and motor learning. Borrowing from the parent disciplines (e.g., psychology, sociology, physics), each of these subdisciplines, among others, began to adopt their own unique research methods, theories, and language, facilitated by the gradual emergence of multiple paradigms and tentative steps

toward qualitative inquiry and critical theory research. Emphasis at this time was on affiliation with the “parent discipline” and away from the practice of physical education. As a result, the field of physical education began to look more like other academic disciplines, but in the process became fragmented, with each subdiscipline becoming increasingly isolated from the others. These beginning trends in the 1960s quickly became the field’s primary structure, a development that has grown since then. One consequence of all of these changes, because of prioritization of the subdisciplinary structure over practice, was the reduction of status of practice-based activities in higher education, leading to a loss of the term *physical education* at many institutions of higher education. It was replaced by subdisciplinary terms such as *kinesiology*, creating distance between what was physical education in higher education and what remained as physical education in schools across the country.

### The Growth of Curriculum Studies

Although these issues were problematic and warranted attention (and still do), this new structure provided an opportunity for curriculum studies in physical education to begin to carve out its own niche. Physical education teacher education (PETE) already had a research base, the aforementioned body of systematic observation studies. A new term, sport pedagogy, which was intended to focus on physical education instruction research, cropped up in the field’s lexicon. Unlike most of the other subdisciplines, PETE and sport pedagogy attempted to bridge the gap between what was left of university physical education and what was going on in schools. Physical education, many argued, was both a discipline and a profession. However, in the eyes of some academics, their work was that of “second class citizens” in a fragmented field.

Although the door had opened for specialization in physical education, the development of curriculum studies in physical education lagged behind PETE and sport pedagogy. The struggle for identity and recognition continued into the 1980s, but during that decade, research on teaching in physical education was finally included in the Big Ten conference on research in teaching physical education at Purdue. However, curriculum studies were

more or less ignored, a point punctuated by one highly recognized physical education scholar who argued against inclusion of curriculum scholarship in one of the leading physical education journals. Undaunted, Ann Jewett, a pioneer in physical education curriculum studies at the University of Georgia almost single-handedly paved the way for a series of biennial curriculum conferences. The American Alliance of Health, Physical Education, Recreation, and Dance soon followed with creation of the Physical Education Curriculum and Instruction Academy, which met (and still meets) yearly, recognizes one distinguished curriculum-instruction scholar each year, invites a recognized scholar to speak, and includes a social gathering of curriculum-instruction faculty. Although not focusing exclusively on curriculum, these developments helped legitimize curriculum scholarship in the field. Meanwhile, the prestigious American Educational Research Association established a special interest group in physical education that also holds yearly meetings and sponsors several awards for scholarly work.

### Issues and Responses

Despite substantial growth in the field and in curriculum studies and a number of studies designed to upgrade curricular and instructional practices, state school physical education requirements have been under attack for years and even more so in the No Child Left Behind era, even threatening survival of the requirement. Moreover, similar concerns have recently spread to some research universities where PETE, sport pedagogy, and curriculum doctoral programs are being reduced or eliminated, affecting the recruitment of PETE, sport pedagogy, and curriculum studies faculty at middle-range institutions. These are ongoing issues.

Three other factors in addition to the threat of a reduced requirement influenced a shift in the organizational structure of physical education: (1) the child obesity issue, (2) lack of adult guidance for many children and youth in nonschool time, and (3) the emerging field of youth development. The result in many schools was two kinds of programs: (1) in-school physical education and (2) extended-day physical activity. Physical education continued as an in-school instructional experience, but physical activity differed significantly

from the in-school version. For example, kids could choose to join or withdraw from physical activity programs. Kids had more choices in the program. Learning could be more project-based as well as more longitudinal in nature. In at least one state, schools now have both a physical education director and physical activity director.

### The Development of Curriculum Models

The structural shift in practice from physical education to both physical education and physical activity gradually began to influence professional preparation in higher education. Programs to “train” youth development professionals sprung up here and there in higher education, eventually spreading to the field of physical education. For example, physical education programs focused on developing physical activity programs; in other words, developing curriculum for children and adolescents in underserved communities began to be offered in masters and doctoral programs at the University of Illinois at Chicago and at the University of North Carolina at Greensboro.

A recent comprehensive review of physical education curriculum and instruction scholarship sponsored by the prestigious Kinesiology and Physical Education Academy praised the growth of data-based knowledge in some curriculum models (described later) and suggested a research agenda for the future. Major initiatives included the design and implementation of a variety of curriculums for different curricular populations, cultural settings, and subject matter; and investigating to what extent these various curriculums enhance or discourage learning of movement and associated processes such as enjoyment and motivation to participate, especially from the students’ perspectives. Although this agenda was noteworthy, it was guided for the most part by the promotion of lifetime physical activity as the primary purpose of physical education, a purpose widely shared by in-school physical educators and PETE faculty, but a contested issue in curriculum studies as reflected in the myriad purposes of curriculum models mentioned later.

This review paid some attention to issues of social justice and inequities in physical education curriculum and instruction, a point expanded by the recent inclusion of diversity and social justice

as standing committees and programs in both the National Association of Kinesiology and Physical Education in Higher Education and the National Sport and Physical Education Association of the American Alliance of Health, Physical Education, Recreation, and Dance.

### Curriculum Models Movement

The curriculum model movement was pioneered by Jewett and jump-started when Daryl Siedentop, a leading positivist scholar (who later became broadened in his work to include curriculum studies) observed that although the “technology of teaching”—including his work as well as many other research activities in PETE and sport pedagogy—was essential, it was insufficient to motivate middle and high school students. An attractive curriculum was also needed.

Thus began the era of physical education curriculum models. Curriculum models rapidly proliferated, each with a different purpose, different content, and different instructional strategies. The publication of a number of books, which began with one book in 1985, reviewed physical education curriculum models in detail. These books differed to some extent in interpretation and overlapped considerably as well, emphasizing the range of ideas and programs.

Part of the confusion can be attributed to philosophical forces both old and new. Fitness, now sometimes broadened to wellness, has been in and out of favor over the years, depending on social forces at the time. The current emphasis on health knowledge and childhood obesity has been instrumental in promoting the fitness-wellness curriculum model.

Interest in the whole child first emerged in physical education as education through the physical. Then, in the 1970s, it was reincarnated as humanistic physical education, and by 1980, its latest reincarnation, teaching responsibility through physical activity, is now viewed as a curriculum model, derived from the work of Don Hellison and others. Play education emerged as a counterpoint to emphasis on the whole child. It was a version of the earlier education of the physical approach—this time centered on the intrinsic virtues of play rather than fitness. The key point was that the subject matter of physical education ought to be

physical activity, and more specifically play, not for instrumental purposes as in the whole child rationale but as an intrinsic benefit. Play education led the way to another curriculum model, sport education.

Originating in England, human movement was first introduced in the United States by a few scholars who viewed it as a philosophical umbrella for the field of physical education. But its influence was arguably greater as a new way to work with elementary school children. Eventually, a new curriculum model, skill themes, was based on the human movement framework.

The early scientific emphasis in physical education influenced the fragmentation of the field into subdisciplines and provided a basis for requiring more scientifically oriented courses in the physical education major, such as exercise physiology, biomechanics, and motor learning. In turn, these courses began to be transformed into scientific lessons in in-school physical education, and this approach is sometimes known as the concepts model.

### Recent Models

Two recent books on curriculum models, one written by Mike Metzler and the other by Jackie Lund and Deborah Tannehill, detail many different curriculum models. The purpose of sport education is to teach youth the best of the organized competitive sport culture to introduce and inculcate positive youth sport practices in all school-age youth and teach students to be competent, literate (know the rules, rituals, traditions), discerning sports enthusiasts. According to this model, best competitive sport practices include providing an organized sport experience and playing time for all kids, not just athletes; keeping team but not individual statistics to emphasize the importance of the team rather than the individual and to promote teamwork; and teaching leadership by gradually shifting responsibility for carrying out team sport tasks to the youth, such as coaching, officiating, and keeping game statistics. In sport education, the typical physical education units are replaced by seasons that are longer than the typical physical education unit to conduct practices, preseason games, in-season games, a postseason tournament, and an end-of-season celebration.

Games for understanding is an orientation that originated in England as an alternative to the typical approach to teaching skills in physical education both in England and the United States and has been modified in the United States and called tactical games. The traditional approach begins with a focus on a specific sport such as soccer or volleyball. Basic skills are demonstrated, drills to practice the skills are conducted, and a game is played. Kids often show little enthusiasm for the demonstration, or drills, they want to play (or, for a few, sit out). Games for understanding, however, begin with a modified game or gamelike task based on a sport form, for example, small-sided games of soccer without goalkeepers or throw-ins. The teacher then builds on this experience either by introducing simple tactical strategies or integrating specific skills development, depending on observations of students' competence in game strategies and skills. This pattern continues as tactics become more complex, skills develop, and the game form begins to resemble the true game. Throughout this progression, students problem-solve situational and sometimes exaggerated tactical applications to learn the complexities of playing the game. Throughout, tactics are prioritized, and skill learning is integrated as necessary. Another departure from traditional practice is the use of game forms (or classifications) such as invasion games, net and wall games, and target games to teach transfer of tactics from one specific sport to another.

As noted earlier, the current emphasis on health knowledge and childhood obesity has been instrumental in promoting a fitness-wellness movement. In turn, exercise, once viewed by many physical educators as optional at best, has become wildly popular in the United States, giving rise to a wide variety of exercise forms and activities. These developments, coupled with the threat of reducing or eliminating the physical education requirement in schools, have spurred the development of fitness-wellness curriculum models. What once was calisthenics at the beginning of class has become a full-blown physical education program at some schools, whereas others often include fitness as part of the curriculum, for example, weight training and jogging units. When funding is available, some schools purchase equipment that resembles that of private health clubs, such as stationary bicycles with heart rate monitors, pedometers to

measure the number of steps a student takes in a day, and more recently video games such as Dance Dance Revolution. Another approach integrates concepts into the fitness-wellness curriculum, so students learn how to exercise, why to exercise, and the amount of time necessary in exercising for health.

Sport and physical education share a history of claiming character development and goals related to social and emotional learning, but these qualities have often been viewed as concomitant learning, that is, automatic when engaging in physical activities. Only recently has this gap between rhetoric and reality been meaningfully addressed. A number of curriculum and instruction designs have appeared in the literature. One of these approaches, teaching personal and social responsibility through physical activity (TPSR), has received considerable attention among physical education/activity scholars and in the literature, including books devoted to describing major physical education curriculum models. It further extends the intention of the education through the physical and humanistic physical education movements.

To use the terminology of the youth development movement with which it is aligned, TPSR embeds life skills in the program's curriculum, whether it is basketball, fitness, dance, or other activities. That means that, if taught effectively, students learn both life skills and physical activity skills and techniques. Those life skills, principles, and values are represented by a simple set of ideas (i.e., "less is more"). The purpose is to teach personal and social development through physical activity, so students are asked to take responsibility for a progression of five responsibilities—respect for the rights and feelings of others, effort and self-motivation, self-direction, helping and leadership, and exploring transfer to other settings. In addition, TPSR contains a daily format with five parts, which include an awareness talk to emphasize taking responsibility, a closing group meeting to evaluate the lesson, and reflection time where students self-evaluate their five responsibilities during the lesson.

Physical education has come a long way since the 1960s and before that. A number of the issues reported earlier continue to plague the field, including academic status and the relevance of practice. On the bright side, the growth and maturity of

physical education curriculum studies and the early steps in promoting diversity and social justice in the field are among the most promising signs for the future.

## PHYSICAL EDUCATION CURRICULUM, HISTORY OF

---

The history of physical education can be seen as an important dimension of the history of curriculum because it treats the story of responses to questions of what is worthwhile in the psychomotor realm. The psychomotor as such is not merely an alternative to the cognitive (intellectual), the affective (emotional), the social, and the spiritual domains of human functioning. Instead, psychomotor realm is an integration of all five, with a foregrounding of the physical. This history can be traced in ways that invoke many issues such as the influence of European sport and Puritan religious values, the role of physical activity for women, the emergence and popularity of sport, dueling versions of the purposes of physical education, and more recently, racial, ethnic, and gender issues. Evolution has certainly occurred, and physical education has established a foothold in schools, universities, and to a lesser extent youth agencies.

Nevertheless, its subject matter and purposes have remained contested.

Although physical education now has a number of curriculum models to choose from as well as a wide range of curricular content such as exercise, sport, dance, and outdoor/adventure activities, these developments occurred gradually over two centuries. Precursors to the field of physical education include the active games of early Greek and Mayan societies, which were often part of prevailing notions of education for life. However, physical education as a field was unknown until the 1800s. In the United States at that time, the dominant forms of physical education were imported from Germany and Sweden. The German system included gymnastics exercises, running, throwing, and rudimentary games, whereas the Swedish system emphasized "medical gymnastics," which purported to have science-based therapeutic effects. Germanic and Swedish systems were called gymnastics, but were unlike gymnastics of today.

Another approach countered the prevailing notion that women were fragile and was illustrated by a book in the 1830s that focused on "calisthenics for young ladies." Still another system combined the scientific gymnastics of the Swedes with women's programs. Aspects of these programs and emergent fitness measurement, strength, and health training approaches were combined at Harvard into a comprehensive approach. During these early days, physical educators represented a variety of backgrounds: medical, YMCA, the ministry, and the Women's Christian Temperance movement.

All of this activity preceded and contributed to what became known as the field of physical education (then referred to as physical training or physical culture). The Adelphi Conference of 1885 brought together the key contributors to organized physical activity programs from the various systems in vogue, including a representative group of women who were strong advocates of physical education, members of the news media, college presidents, and clergy. This conference is recognized as the birthplace of physical education. A new professional organization, the Association for the Advancement of Physical Education, was founded at the Adelphi Conference. This organization provided programs to prepare instructors of physical education, among the first being the Department of Physical Education at Amherst

College. The YMCA was also an early player in training physical education instructors, leading to the creation of Springfield College in Massachusetts. Soon, Springfield began to be recognized as a major professional preparation institution for the development of physical education, fitness, and sport practitioners, a reputation that has continued.

These and other activities solidified and extended a unified U.S. physical education influenced by John Dewey and others. The first doctoral program in physical education was also established at Teachers College, Columbia University in this era.

Gradually, building on the teacher education pioneer work at Amherst, Springfield, and elsewhere, physical education began to be considered a school subject. Near the beginning of the 20th century, California became the first state to require physical education in schools. Today's popular sports were not part of physical education until the 20th century, although sporting games did attract interest and spectators much earlier. The urbanization of the United States and the Civil War contributed to the rapid growth of organized sport. At first, students rather than teachers lobbied for sport programs, but soon games were being played on college campuses, and individual sports created organizations, standards, and rules. The rebirth of the Olympic movement in the late 1800s further fueled the sport movement.

When physical educators began to include sports, it led to a philosophical conflict between advocates of exercise for health and those for sports, which was exacerbated by a growing conflict between physical educators and coaches. This conflict became even more contentious as sport advocates, reminiscent of ancient Greece, began to argue for the social, emotional, and cognitive as well as physical benefits of sports, a movement known as education through the physical. Such attributions were not new. As the education through the physical movement gained momentum, health and fitness advocates argued for more emphasis on the physical outcomes of various forms of exercise and were skeptical of the holistic claims of the other side. Their view became known as education of the physical. This debate lingered into the 1950s and beyond, and in the 1970s resurfaced with the emergence of humanistic physical education, aided by the humanistic education movement.

It was the middle of the 20th century before a step toward integrating African Americans into sport programs was attempted, an event that by no means solved discrimination problems but did have widespread ramifications for the society and for other minorities that continue. Legislation known as Title IX also profoundly affected sports by mandating that women receive a more equal share of the resources supporting sport programs. Title IX also affected school physical education by requiring classes to be coeducational to receive funding, a law that was evaded in some, perhaps many, school districts until compliance gained a foothold.

Although the history of physical education curriculum has had ebbs and flows, rediscovering and re-naming previously enacted ideas and strategies, it has also evolved to a point in which contemporary models often address the place of physical activity in the context of life, not sport or exercise in isolation. As such, today's models of physical education push toward enabling conscious attention of teachers and learners on the development of better health in a holistic emphasis on self-realization and social responsibility.

## PIAGETIAN THOUGHT

---

Jean Piaget (1896–1980) was one of the 20th century's most influential educational theorists, with a particular emphasis on how children learn. He was not just a learning theorist though; he was also—and indeed foremost—a philosopher and logician, theoretical biologist, developmental psychologist, and cognitivist. His magnum opus is

*Biology and Knowledge*, followed by his *Behavior and Evolution*. In these, he lays out his “genetic epistemology,” where he talks of the process of cognitive development in terms of transformations. These transformations hold importance for curricularists.

For Piaget, transformative development in humans (children especially) was development that moved actions (and reactions to actions) from one stage or level to a new, higher stage or level. Such a hierarchal process was allied with (and indeed may have been heavily influenced by) his PhD study on how mollusks (snails) reacted to a change in their environment. Piaget observed the snails did not react immediately to a change in environment; rather they *assimilated* the environmental change into their own, patterned ways of operation. At a certain, undetermined point, though, enough environmental change encouraged the mollusks to *accommodate* themselves to the environmental change. This assimilation/accommodation process, *interactive* by nature, became the heart of Piaget’s epistemology. He called it “genetic epistemology,” referring to the fact that behavior, especially, deep-seated, genomic, lasting behavior (a change of schemas or ways of operation), could not be imposed as the Lamarckians/Skinnerians believed, nor was it random as the Darwinists/neo-Darwinists asserted but would develop via an *interaction* of environment and subject (animal/person). This interactionist approach was applauded by Ilya Prigogine, an early contributor to chaos and complexity theories, and is much appreciated by Dewey scholars who emphasize inter- (or trans-) action as the way children learn.

Piaget believed that children’s learning is organized around their ability, over time, to develop logical and abstract thinking—for him (as a logician), the epitome of adult thinking. His stages (really *schemas* or ways of operation) are *sensomotor* (0–2) where the child coordinates bodily reflexes; *preoperational* (2–6/7) where the child focuses on self; *concrete operational* (6/7–11/12) where the child/youth begins to develop a systems view, becoming aware of more than self but limited in this thinking to concrete instances; and *formal operational* (11/12–) where (ideally) mature, abstract, rigorous, logical thinking becomes operational. The sense of “progression” in this process captivated U.S. audiences, especially childhood

teachers and theorists. “Developmentally appropriate practices,” became a mantra for childhood educators. Childhood educators found themselves caught—they wanted to use operations that fit the stages the child was in; parents and often administrators want to “aid” the child to move through the stages quickly. The American way, as Piaget labeled it, was to move children as quickly as possible through the stages. Piaget, though, with his firm grounding in a biological, interactionist process—one where the genome has its own ways of operation, and maintaining his theory of genetic epistemology, affirmed that one could not “teach” a child out of one stage and into the next. Movement of this sort happens not by force or even by enticement but when the child’s cognitive structure “desires” such a change. The transformation happens individually, unspecified, and “tout ensemble.”

This sense of a sudden, total change of schemas/worldviews/ways of operation/structures is much akin to the work being done in complexity studies at the Santa Fe Institute, especially by Per Bak and Stuart Kauffman. Piaget’s interactionist approach—a *tertium quid* alternative to both (behaviorist) imposition and (benevolent) neglect—can be seen, along with Dewey’s inter- (trans-) actional approach as a forerunner of the complexity theory approaches being developed today. Curricularists utilizing the insights of complexity theory believe meaningful, lasting learning occurs not by imposition (direct instruction) nor randomly (benign neglect); rather, it occurs as the result of an interactive, creative, and dynamic tension occurring between subject and object, self and other, person and environment.

Within his genetic epistemology, Piaget labels his interactionist approach Equilibration. Here a child or young learner “seeks” a harmony within the operatory schema he or she is using. This zone of comfort is disturbed either by chance or pedagogical design and a sense of disequilibrium sets in; through the active process of assimilation/accommodation, a new, more comprehensive (and logical) stage/schema emerges. Equilibration occurs as the original stage/schema is re-equilibrated. Regrettably, few educators have seen the importance of this process.

Although in this process, it is disequilibrium that is “the driving force of development,” there

is overall a sense of active seeking, of *purpose* that Piaget posits to mollusks and humans. In one of his last writings, a book done with and finished by Rolando Garcia, Piaget explores this notion of *purpose*. Piaget believes that from an early age (when the child can distinguish relations), the young child is purposeful in his or her actions—he or she not only acts but acts with *intentions*. The “illogic” adults find in (and are often frustrated by) a child’s operations are, from another point of view, the child’s way of operating within his or her schema in a purposeful way. Over time, these operations become more and more “logical.”

For curricularists, the art is one of looking at not only the child or learner’s actions but also ferreting out his or her intentions. Further, it means allowing/encouraging the child/learner to utilize well the power of the schema present while also providing at the right time and in “just the right amount” those perturbations necessary for new and more comprehensive schema to emerge. Such is the legacy Jean Piaget has left us.

## PLACE-BASED CURRICULUM

---

Place-based curriculum can be viewed as a holistic approach to education, conservation, and community development that uses the local community as

an integrating context for learning. Place-based curriculum seeks to foster a partnership between schools and communities. Historically, it has focused on environmental, social, and economic change, using a project-focused approach tailored by local people to local realities. It has been referred to as community-oriented schooling, ecological education, and bioregional education. The current notion is based on the concept that people should know and understand the historical, sociological, ecological, and political traditions of the places they inhabit. In the current atmosphere of schooling, place-based education is seen as a primarily rural concept. Ironically, the most successful and oldest forms of place-based curriculum are urban. This entry is a brief narrative of place-based curricula, a discussion of its philosophical underpinnings, and examples of place-based curriculum and their place within the current educational and social policies.

The 1959 Conant report was extremely influential in restructuring the small high school, calling for consolidation of small schools and teaching of subject-based lessons (to compete in science and math). James Conant advocated consolidation and graduating classes of 100 or more to have diversified curricula, effectively ending integrated subjects (crucial to place-based education) and focus on disciplines. In the 1960s, place-based curriculum was crucial to the foundation of Head Start in Mt. Beulah, Mississippi. Alongside this formal education, informal groups used place to drive social change. Freedom Schools in the South, civil rights workers and their organizations, and urban workers redefined the idea of place-based curriculum.

In New York City, urban plight and poverty led the city to allow schools to be run by local school boards (Brownsville), focus on ethnic populations, and allow alternative school within school buildings. Examples, such as Central Park East (founded by Deborah Meier), reinvigorated place-based curriculum in schools. In Berkeley, Chicano Studies emerged as a high school major; and the Black Panthers began running community schools in Oakland. In Texas and Louisiana, ethnic groups (Vietnamese and Mexican) founded language schools. In 1963, Coral Way Elementary (Miami-Dade, Florida, County Public Schools) became the first bilingual school (educating children in the day and parents at night). The North Dakota Study

Group (founded by Vito Perone) became a hub for place-based curricula and evaluation of place-based schools. However, in the 1970s, schooling became less focused on place and more on a de facto national curriculum. During this time, rural depopulation, the farm crisis (1980s), and the changing rural landscape led many schools to turn to place-based education. Consolidation and Hispanic migration led rural schools to rethink ideas of place and identity. Currently, place-based education has reemerged in urban areas through charter and neighborhood schools and in rural areas (especially in Appalachia and the Great Plains) of extreme poverty.

Currently, reformers and researchers make the case that rural universities should specialize in rural teacher preparation because preparing lessons anchored in community circumstances and dilemmas is sophisticated pedagogical work. Concurrently, urban schools seek total control of local or neighborhood schools and integration of local culture in the curriculum. Place-based education has been enlivened by the current push for environmental or green education. Local sustainability has become the driving force of local curricula based on local needs. For example, the state of Iowa has become involved in curricula that seek to improve water pollution from local farms. In West Virginia and rural Pennsylvania, there are current efforts to increase local studies of small communities, especially coke, steel, and coal industries. In California, an effort is underway to record and discover local languages (many of which are indigenous and disappearing) through school programs involved with local action groups.

Even with these unique nationwide efforts, four major issues persist. The first is the rigor of place-based curriculum that does not go through traditional curriculum adoption processes. Second is the conflict that studying the local at the expense of the global hurts learners who are more intimately tied to a global economy than to a regional one. Third is the place of certain groups within the local landscape and curriculum. Children of color or diverse ethnicities, religions, or exceptionalities find themselves not included. Ironically, the national curriculum (federal law) has borne the onus for curricular inclusion. Fourth is how to define the role of nonschool organizations such as community action groups, hospitals, clinics, 4-H,

Future Farmers of America, Rotary Clubs, and University Extension within the local curriculum. Also, and more importantly in an era where all curriculum in K–12 schooling (and in higher education) must be measured or assessed, how do we measure the impact of learning when all programs are unique to place?

Place-based curricula has thematic patterns that include (1) cultural studies, (2) nature studies, (3) internships and entrepreneurial opportunities (a chance to think about local vocational options), and (4) sustainability (examples include the Foxfire project, run by the teachers and students in Georgia in the 1970s). In general, contemporary schooling in the United States has been reformed to respond to the imperatives of globalization and economic growth. Curriculum developers proposed an industrialized factory model or urban model as the models of public education in United States—and this model has dominated not only 20th-century developments but continues to do so, thereby questioning the place of place-based curriculum.

## *PLACE CALLED SCHOOL, A*

---

John Goodlad's *A Place Called School*, published in 1984, is the chief fruit of what is generally

considered the most extensive on-site examination of U.S. schools ever undertaken. Deftly combining quantitative and qualitative data, Goodlad offers both a robust portrait of that place called “school” and a broad agenda for improvement. Goodlad’s account of the commonplaces of schooling, the competing functions of schools, the explicit and implicit curriculum, and the circumstances of teaching make it a landmark in curriculum studies.

The 4-year “Study of Schooling” was motivated in part by Goodlad’s concern that many prior efforts at school improvement had proceeded in ignorance of how schools actually function. In contrast, the study that Goodlad devised is legendary in scope, drawing data from 7 geographic areas, 13 communities, 38 schools, 1,350 teachers, 8,624 parents, and 17,163 students. Although the study generated many specific technical reports, *A Place Called School* is Goodlad’s synthesis of his key findings. Combining quantitative data—such as proportional measurements of time spent on instruction, behavior management, and social activity—with thicker, qualitative descriptions, Goodlad illuminates the characteristic features of U.S. teachers, classrooms, and curricula.

*A Place Called School* confirms much of our conventional wisdom about schools and their organization, but the documentation of these “commonplaces” (a term adapted from Joseph Schwab) is one of Goodlad’s achievements. He helps us to see, name, and understand the elements that make up the underlying “grammar” of schooling (to use David Tyack’s later term). For example, Goodlad reminds us that schools fulfill two fundamentally different functions, the custodial and the educational, and that the latter comprises competing academic, intellectual, social, personal, and vocational aims. He shows us teachers who are disconnected from each other, but at home in their classrooms; parents relatively pleased with their child’s school, while pessimistic about the status of schooling in general; dull, didactic instructional practices and disengaged students. It is not only that Goodlad brings such commonplaces into sharp focus, but that his study offers the data to establish them as generalizable features of schooling, rather than simply properties of this or that school. His careful mapping of the interpersonal, political, and phenomenological landscape of

schooling provides a crucial check against headlong school reform.

Goodlad also warned that reform must not be attempted in a piecemeal fashion, but must be mindful of the interactions among the many components of the whole. His notion of the school as a “total entity” has been important for curriculum studies. For Goodlad, curriculum must be considered in the context of the whole school culture. For example, a curricular reform may fail because it ignores how teachers are trained. Goodlad unapologetically delivers the bitter medicine that school improvement is necessarily a complex and extended undertaking.

Goodlad’s own proposals for reform have unfortunately been somewhat overshadowed by his comprehensive and perspicacious portrait of the school. Clearly tied to the study’s data, his proposals in fact merit careful consideration. Goodlad offers two kinds of proposals for reform. The first type involves adjustments to schools as they currently operate (for example, he suggests shifting more authority to local school personnel, and enabling teachers to spend more time preparing lessons during the school day), and the second type challenges basic assumptions of current schooling practice on a more fundamental level (for example, having children attend schools from age 4 to age 16, establishing nongraded classrooms where older students help younger students, and integrating school with other community educational institutions such as the home, television, and public library).

*A Place Called School* paints a detailed, data-driven portrait of school that outlines the common practices and stubborn structures in schools across the United States. Goodlad’s reform proposals flow from this portrait and from his insistence that we think of schools as integrated wholes. That this portrait resonates as much today as it did a quarter century ago is a tribute both to the robustness of Goodlad’s data and the resilience of his object.

---

## PLANNED CURRICULUM

---

*Planned curriculum* refers to documents that shape the content to be covered when teaching. These documents arise out of policy environments and reflect what is deemed required or necessary for students to learn at specific levels of education or educational settings. Typically, planned curriculum documents are created by governments, publishers of subject matter series, publishers of assessments, or boards of education. Planned curriculum can be categorized in two ways: curriculum that is prescribed or curriculum that is subscribed. Prescribed planned curriculum expects teachers to follow a defined set of objectives or outcomes, whereas a subscribed planned curriculum provides outcomes or objectives but allows for some teacher selection. Typically, planned curriculum is mandated at some level for teachers to use in their teaching and teachers are supervised in some manner to ensure their use of the planned curriculum.

In some countries or jurisdictions, the government mandates a planned curriculum that teachers are legally bound to implement. In other contexts, school boards or jurisdictions take up the published curriculum and expect teacher implementation. Implementation of planned curriculum places teachers within a policy conduit where curriculum is seen as something beyond the lives of teachers and learners and reduces the professional autonomy of teachers to choose curriculum that supports learners in a learning relationship.

The development of official planned curriculum may involve teachers, curriculum specialists in school jurisdictions, and government curriculum specialists. In the development of curriculum

documents, to connect planned curriculum to the field, teachers may be asked to “test drive” new curricula in their classrooms and suggest refinements. The inclusion of practicing teachers has located these curriculum documents in teacher practice; however, by nature, planned curriculum is generalized and treats learners as a homogenized group. Planned curricula are a purposeful progression of a generalized trajectory of concepts that build one on the other as learners become more sophisticated or knowledgeable in a subject area. The subject matter is fixed at different levels and subsequent levels assume knowledge gained at prior levels in the plan. This ties to evaluation and establishes benchmarks for assessing learners and monitoring teacher practice.

Because of this, planned curriculum is often narrow and rigid by nature and, because of the scope of a planned curriculum, cannot be responsive to specific learner and teacher situations. Historically, planned curriculum was couched in terms of objectives, which set direction for teaching practice, but there has been a shift to a language of outcomes. This is a significant difference in planned curriculum because it focuses on learners and what they will be able to produce at the end of a curriculum enacted by a teacher within the policy conduit. Planned curriculum is not relational in its structure beyond a vague expectation that teachers and learners in an educational relationship will achieve set objectives or outcomes. A planned curriculum by nature does not acknowledge the possibility of true relationship where teachers provide a curriculum responsive to the needs of individual learners. In tension with planned curriculum is the lived curriculum of the people involved in the curriculum making that arises out of educative situations.

Planned curriculum is transformed by the lives of learners and teachers in their realities and the decisions they make, within the context of the complexity of their lives lived alongside each other. Tensions of situation and continuity in classrooms shape the experience of teachers and learners and planned curriculum is but one part of these tensions. As an official document, it is often assumed that a planned curriculum can be mastered, and learners assessed on their mastery of the objectives or outcomes mandated in the document; however, there is much in the lives of learners and teachers that interrupts this concept of curriculum as

planned. Teachers as curriculum planners are the most responsive creators of curriculum as they negotiate the formal planned curriculum of governments and publishers within their practice alongside the lives of learners.

---

## POLITICAL RESEARCH

---

Education is not a neutral, technical activity. Rather, as an act of influence, it must be seen as an ethical and political act. To understand this, we need to think *relationally*. That is, understanding education in general and curriculum studies in particular requires that we situate them back into both the unequal relations of power in the larger society and the relations of dominance and subordination—and the conflicts—that are generated by these relations. Thus, rather than simply asking whether students have mastered a particular subject matter and have done well on our all too common tests, we should ask a different set of questions: Whose knowledge is this? How did it become “official”? What is the relationship between this knowledge and who has cultural, social, and economic capital in this society? Who benefits from these definitions of legitimate knowledge and who does not? What can we do as critical educators to change existing educational and

social inequalities and to create curricula and teaching that are more socially just? These kinds of questions are not new. They have a very long tradition in education and are connected to a question that was put so clearly in the United States by radical educator George Counts when he asked, “Dare the school build a new social order?”

One of the most important steps in taking these questions seriously is to engage in what has been called in cultural theory an act of “repositioning.” Thus, the framework politically and educationally progressive educators have employed in essence says that the best way to understand what any set of institutions, policies, and practices does is to see it from the standpoint of those who have the least power. Seeing the world from the standpoint of the dispossessed asks that we also rigorously scrutinize the ways in which all of our dominant institutions function, including schools. Although this may be discomfoting, it is a crucial step if we are to move forward in understanding the politics of curriculum and the entire schooling process. It also redefines the role of the critical scholar as someone who is an *organic intellectual*—that is, someone whose work is meant to support the struggles of the dispossessed.

In terms of the curriculum, this act of repositioning has significant implications. The curriculum is itself part of what has been called a selective tradition. That is, from that vast universe of possible knowledge, only some knowledge gets to be “official knowledge,” gets to be declared “legitimate,” as opposed to simply being “popular culture.” There is a strong, but exceedingly complex, relationship between a group’s social and cultural power and its ability to set the terms of curriculum debates and to have its values, culture, and histories seen as the backdrop against which all other values, culture, and knowledge are to be measured. The results of this are not preordained, however. The curriculum is always the result of constant struggle and compromise. But this is not a level playing field; differential cultural and economic capital does count.

Second, this political structuring is not only seen at the level of content. It is also visible in the ways in which the curriculum is organized and evaluated. As a number of critical scholars have demonstrated, curricular *form* also represents the social and cultural glue, the ways of being in the world,

of particular classes and class fractions and of dominant race and gender relations. Indeed, most of the debates about the form the curriculum should take and how it should be evaluated are often really arguments within groups who already have considerable power.

Third, the larger politics in which the curriculum partakes, indeed the politics of education in general, is visible in the relationship between schooling as a set of institutions and the social, sexual, and racial divisions of paid and unpaid labor. Even though many educators actively work to promote the (individual) mobility of their students, it is still the case that education functions to roughly support or at least not actively interrupt these larger social divisions. As nearly three decades of research has documented, this is neither a mechanistic process in which education has no relative autonomy, nor are teachers and students passive in the face of this. Yet, this said, it is still absolutely crucial to remember that on the whole the education system works much more effectively for those social groups that already have cultural and economic capital and that are able to convert one to the other.

This may be the result of differential funding, the economic and cultural advantages affluent groups have in guaranteeing that the cultural “gifts” their children possess are those that are both recognized in school and are connected to the changing dispositions and knowledge needed by dominant institutions, the histories of mistrust and alienation that dispossessed peoples rightly have when interacting with dominant institutions, the intricate politics of popular culture, and much, much more. The reasons are historically and culturally complicated, but the results are visible in what have been so correctly called the “savage inequalities” in this society’s schools.

These social divisions go beyond the relatively essentializing categories of class, race, and gender, of course, to include sexuality, “ability,” age, nation, bodily politics, and so on—each of which is in constant interaction with the others. These kinds of “things” are often separable only at an analytic level.

And this point leads to the fourth way in which education, curricula, and teaching are political. This involves the ways in which the school participates as a workplace in the historic construction of

teaching as classed, gendered, and raced labor. Thus, in many nations of the world, the majority of teachers are women. This is especially the case at the elementary school level. We cannot understand why curricula and teaching are controlled in the ways they are unless we also recognize that work that is done by women is unfortunately often subject to lower pay, less respect and autonomy, and more social blame. The fact that historically working-class women and men saw teaching as a path to class mobility needs to enter into the argument as well. Also, the history of teachers of color, especially the fact that African American, Chicano/a, Asian American, Native American, and other populations were historically often excluded from teaching jobs or were placed in segregated underfunded schools, and had to struggle for decades to gain recognition as teachers—all of this documents the fact that schools exist as part of a racialized and racializing state, a gendered state, and a classed state. The fact that gay and lesbian teachers are still at risk of losing their jobs in many communities documents that the state is part of a political apparatus that polices sexuality in its employment practices as well.

Schools, then, are not separate from political and moral economies, but are very much part of them. In essence, the separation we make between the politics of education and the politics of the larger society is not all that useful. The separation is an artificial one, since schools are crucial parts of that larger society. Indeed, not only are they among the central institutions that make it up, they have played extremely important roles in providing arenas for the very formation of social movements that have challenged dominant power relations.

That this occurs in and through the state leads me to the next political realm. Formal schooling by and large is organized and controlled by the government. This means that, even aside from the role of schooling as an arena of class, gender/sex, and race mobilizations or as a place of paid employment, by its very nature the entire schooling process—how it is paid for, what goals it seeks to attain and how these goals will be measured, who has power over it, what and how textbooks are approved, who has the right to ask and answer these questions, and so on—is by definition political. Thus, as inherently part of a set of political

institutions, the educational system will constantly be in the middle of crucial struggles over the meaning of democracy, over definitions of legitimate culture, and about who should benefit the most from government policies and practices. That this is not of simply academic interest is made more than a little visible in the current attempts to institute neoliberal reforms in education (such as attempts at marketization through voucher plans) and neoconservative reforms (such as national curriculum and national testing, a return to a “common culture,” and the English-only movement).

This fact points to the final part of this discussion. Education is thoroughly political in an even more practical way. In order to change both its internal dynamics and social effects and the policies and practices that generate them—and in order to defend the more democratic gains that committed educators and activists have won over the years—we have learned that we need to act collectively. Multiple movements around multiple progressive projects surrounding education and its role in all of the complex politics to which I have pointed here are either already formed or are currently in formation. The lesson here is clear. Collective dilemmas warrant collective political responses.

Understanding these complex politics is crucial, but it is but a first step. Taking this understanding seriously asks us to then take up a series of responsibilities or “tasks” if we are to go further.

In general, there are seven tasks in which critical analysis (and the critical analyst) in education and in curriculum studies must engage:

1. It must “bear witness to negativity.” That is, one of its primary functions is to illuminate the ways in which educational policy and practice are connected to the relations of exploitation and domination—and to struggles against such relations—in the larger society. This can be summarized as a simple injunction: Tell the truth.

2. In engaging in such critical analyses, it also must point to contradictions and to spaces of possible action. Thus, its aim is to critically examine current realities with a conceptual/political framework that emphasizes the spaces in which more critically democratic (what might be called “counterhegemonic”) actions can be or are now going on.

3. At times, this also requires a considerable expansion of what counts as “research.” Here I mean acting as “secretaries” to those groups of people and social movements who are now engaged in challenging existing relations of unequal power or in building powerful educational programs that challenge our accepted ways of doing curriculum, teaching, and evaluation. This is exactly the task that has been taken on in the thick descriptions of critically democratic school practices in the United States that have been done by many curriculum scholars and activists. It is also found in the similar critically supportive descriptions of the transformative reforms such as the Citizen School and participatory budgeting in Porto Alegre, Brazil, one of the centers of impressive work in critical education internationally.

4. One of the tasks of a truly counterhegemonic education and research is not to throw out “elite knowledge,” but to reconstruct its form and content so that it serves genuinely progressive social needs. This is a key to another role “organic intellectuals” might play. Thus, we should not be engaged in a process of what might be called “intellectual suicide.” That is, there are serious intellectual (and pedagogic) skills in dealing with the histories and debates surrounding the epistemological, political, and educational issues involved in justifying what counts as important knowledge. These are not simple and inconsequential issues and the practical and intellectual/political skills of dealing with them have been well-developed. However, they can atrophy if they are not used. We can give back these skills by employing them to assist communities in thinking about this, learn from them, and engage in the mutually pedagogic dialogues that enable decisions to be made in terms of both the short-term and long-term interests of oppressed peoples.

5. In the process, critical research has the task of keeping traditions of critically democratic work alive. In the face of organized attacks on the collective memories of difference and struggle, attacks that make it increasingly difficult to retain academic and social legitimacy for multiple critical approaches that have proven so valuable in countering dominant narratives and relations, it is absolutely crucial that these traditions be kept alive, renewed, and when necessary criticized for their

conceptual, empirical, historical, and political silences or limitations. This involves being cautious of reductionism and essentialism and asks us to pay attention to movements that deal with multiple kinds of inequalities. This includes not only keeping theoretical, empirical, historical, and political curricular traditions alive but, very importantly, extending and (supportively) criticizing them. And it also involves keeping alive the dreams, utopian visions, and powerful critical reforms that are so much a part of these radical traditions.

6. Keeping traditions alive and also supportively criticizing them when they are not adequate to deal with current realities cannot be done unless we ask “For whom are we keeping them alive?” and “How and in what form are they to be made available?” All of the things that were noted earlier in this tentative taxonomy of the tasks of political research and researchers require the relearning or development and use of varied or new skills of working at many levels with multiple groups. Thus, journalistic and media skills, academic and popular skills, and the ability to speak to very different audiences are increasingly crucial.

7. Finally, critical educators and curriculum researchers must *act* in concert with the progressive social and educational movements their work supports or in movements against the dominant assumptions and policies they critically analyze. One must participate in and give one’s expertise to movements surrounding struggles over what schools do, how they do it, and how we evaluate it. It also implies learning from these social movements. This means that the role of what has historically been called either the “unattached intelligentsia” or someone who “lives on the balcony” is not an appropriate model. Of course, our intellectual efforts are crucial, but they cannot stand aside, neutral and indifferent, from the struggles in which the future of the world is at stake.

These seven tasks are demanding and no one person can engage equally well in all of them simultaneously. What we can do is honestly continue the attempt to come to grips with the complex intellectual, personal, and political tensions and activities that respond to the demands of this role. And this requires a searching critical examination of one’s own structural location, one’s own

overt and tacit political commitments, and one’s own embodied actions once this recognition in all its complexities and contradictions is taken as seriously as it deserves.

This will not be easy. But critical reflection and action in curriculum studies and in education in general has a long history of people who have devoted their lives to keeping this tradition alive inside and outside of education. Our responsibilities are the same.

## POSTCOLONIAL THEORY

---

Postcolonial theorists write in different disciplinary areas such as political theory, cultural

studies, literature, history, and women's studies. Postcolonial theory engages issues of race, class, gender, culture, language, and nation in terms of empire and imperialism, popular culture and diaspora, identity, representation, and multiculturalism. Scholars writing in the field of curriculum studies who engage postcolonial theory have noted that education itself is deeply implicated in the project of colonialism and plays a role in transmitting colonialist structures and practices. For instance, a number of scholars (such as Philip Altbach, Dipesh Chakrabarty, Greg Dimitriadis, Cameron McCarthy, Linda Tuhiwai Smith, Sofia Villenas, Gauri Viswanathan, among others) have critiqued Eurocentrism in education and spoken to the issues of disregard for and marginalization and loss of indigenous knowledge and ways of knowing, the internalization and reproduction of colonialist structures and practices, and the resultant contradictions and contestations in curriculum frameworks and teaching practices. Witness, for instance, the dominance of Eurocentric writings and perspectives in such subject areas as literature and history. As U.S. curricularists well know, peoples of color, women, and lesbian, gay, bisexual, and transgender (LGBT) populations have had to fight battles—and continue to do so—to have their struggles, stories, and perspectives represented in both the larger social context of the United States as well as in curriculum and teaching. In this process, various populations on the margins may form coalitions, and they may also find themselves in conflict with each other as they seek to create spaces of self-representation. Thus, the dynamics of rethinking and emerging from oppression and colonization also lead to new struggles and hierarchies in school and society.

Such scholars as Edward Said, Gauri Viswanathan, and Dipesh Chakrabarty, among others, reveal that colonialism has shaped discourse, disciplinary knowledge, education, and the use of language. Although the era of colonial rule has ended, its effects—such as poverty, illiteracy, “underdevelopment,” and transnational migration—continue to remain present. In the digitized, globalized 21st-century context, colonization may also be understood in terms of control and dissemination of mass media, technology, popular culture, and so on—for instance, the prevalence of U.S. popular culture in many parts of the world.

Specifically, then, postcolonial theory focuses on interrogating and unpacking such effects of colonialism as the exploitation of human and natural resources and the shaping of discourses, education, language, and identity. Postcolonial theory also addresses contradictions arising from colonization such as the internalization of the colonizer by the colonized, and the fact that the aftermath of colonialism is evident in the colonizing countries and peoples as well as in the former colonies. For instance, the colonized may acquire the language and behaviors of the colonizer and learn to hold them as “superior” to their own language and ways of being, and, even today, racial and cultural tensions are evident in such Western countries as the United Kingdom. Given that the colonized internalize the colonizer, it follows that, even as they resist colonization, the colonized submit to and participate in the realization of the colonial relationship. Furthermore, postcolonialists such as Gloria Anzaldúa and Homi Bhabha have talked about how, individuals, finding themselves in the “borderland” and at the “interstices” (in-between spaces) in (post)colonial contexts, negotiate hybrid identities and cultures. Finally, the logic of colonization is incomplete and self-contradictory, and the colonized express their resistance in direct and subtle ways. For instance, even as the colonized might be forced to adopt the language and ways of the colonizer, they adapt and modify them in subtle and even direct ways, thus subverting colonial authority and ensuring that it is never complete.

In an era of globalized capitalism and hyperdigitization, the twist in (post)colonial relations is that the formerly colonized others also consume and reproduce “Western” cultural, material, and curricular artifacts in their home countries, even as they continue to supply labor, services, “ethnic goods,” and “raw materials” to the former colonizers. For instance, although various electronic gadgets or garments may be assembled and manufactured in “third world” or “developing” countries and exported to the “West,” citizens of those countries also consume, emulate, and appropriate “Western” popular culture and ways of being.

Postcolonial theory also discusses how colonization operates at both the systemic and the individual levels. Following such scholars as Frantz Fanon and Kelly Oliver, for instance, we understand that both body and psyche are shaped by

colonization. In particular, feminist postcolonialists, such as Gloria Anzaldúa, bell hooks, Chandra Mohanty, and Trinh Minh-ha, among others, have discussed the affective, psychic aspects of colonization and related struggles in the process of decolonization. For instance, the struggle to unlearn internalized hierarchies of “superior” and “inferior,” rethink “us” and “them” binaries (in terms of race, gender, nation, and so on), and arrive at new understandings of self and other results in dissonance at the intellectual level and emotional conflict within the self.

Several education scholars have articulated similar critiques of the implicatedness of multicultural education itself within extant relations of power. For instance, researchers such as Cameron McCarthy and Nina Asher, among others, have argued that multicultural education discourse and practice will be truly effective in enabling students and teachers to rethink hierarchical, oppressive relations of power only when they emerge from perspectives that are rooted in Eurocentrism, cultural relativism, and cultural pluralism to move toward a critical frame premised on rethinking unequal relations of power in educational and social contexts. A major conundrum that emerges here, then, is this: If educators and cultural workers themselves are implicated in systems of education that are rooted in Eurocentric, colonialist, and oppressive traditions, then how can they rethink and break out of this frame? What are the implications in terms of theory, practice, inquiry, and policy?

Postcolonial theory offers curriculum studies workers useful ways to rethink curriculum and pedagogy. At the broader level, it pushes scholars and teachers to question and re-vision curriculum in terms of history, geography, literature, language, and so on. In terms of practice, it educates them about historically marginalized peoples, knowledge systems, and perspectives, and offers ways of engaging the same via pedagogies centered on dialogue and self-reflexivity. For instance, several of the publications available from *Rethinking Schools*, offer both critical analyses of issues pertaining to race, class, gender, immigration, globalization, and so on, as well as specific strategies and resources for classroom teaching. The increasing interest in engaging postcolonial theory to inform education is evidenced also by the formation, a few years ago, of the Postcolonial Studies and

Education Special Interest Group of the American Educational Research Association. Scholarship in the curriculum field that is informed by postcolonial theory engages questions of identity and representation; race, culture, and nation; gender; and class, in relation to historical and geographic contexts. Postcolonial theory—and especially feminist postcolonial theory—emphasizes the need for a self-reflexive engagement with difference(s) in curriculum, pedagogy, and inquiry. Thus the work of transformation, moving toward equity and justice needs to happen in both the social/exterior realm and in the individual/interior realm. Rather than contributing directly to large-scale policy efforts, curriculum work that engages postcolonial perspectives is useful in providing exemplars for successfully rethinking relations of power and serving as a springboard for building coalitions.

Recent work in the U.S. curriculum field has emphasized the need to engage worldliness and internationalization. This is particularly critical in the hyperdigitized, globalized, 21st-century context in which high-speed transnational exchanges—economic and informational—are the order of the day, even as actually crossing geographic borders is becoming increasingly difficult. Engaging postcolonial theory allows students and teachers to see that such binaries as “East” and “West” are not pure and that curricula, texts, and identities, including their own, are shaped by history, geography, and economics.

## POSTMODERN HISTORIOGRAPHY

---

Postmodern historiography designates an array of approaches to historical inquiry that eschew modern historiographical assumptions. Modern historiographical assumptions rejected by postmodern historiography include teleology, coherence, totalizing (or “grand”) narratives, determinism, progress, truth, realism, objectivity, universality, and essentialism. Postmodern historiographical approaches have been described variously as counterhistory, metahistory, critical and effective history, new historicism, and new cultural history. Postmodern historiography is exemplified most notably in the works of Friedrich Nietzsche, Michel Foucault, Hayden White, and Stephen Greenblatt.

Postmodern historiography is relevant to curriculum studies for its influences on curriculum history and its contributions to theories of knowledge, particularly with respect to purposes of inquiry, foci of study, and epistemological commitments.

### Purposes of Inquiry

Postmodern historiography is generally not a truth-seeking endeavor. In that way, the purpose of postmodern historiography is different from modern historiography, which subscribes to the assumption that the purpose of scholarly inquiry is the search for truth (or truths), and truth is the proper basis for knowledge. The search for truth(s) in modern historiography is made apparent in its attention to methodological rigor, evidence, validity, documentation, and predictive power. In contrast, postmodern historiography is conducted and evaluated on criteria other than those that have been established for truth-seeking approaches to inquiry.

Postmodern historiography complicates the search for truth(s) by using parody, irony, complexity, poetry, deconstruction, narrative analysis, and political critique. One alternative to the search

for truth *Wirkungsgeschichte*, which Jürgen Habermas calls “critical history” and Mitchell Dean calls “effective history.” In Nietzsche’s version of critical and effective history, the purpose of historical inquiry is neither to establish a version of truth, nor to correct errors in the historical record, but rather to dismantle dominant claims to truth and incite critical questioning. The purpose of such postmodern historiography is to provoke, inspire, and galvanize readers, so the genre of postmodern historical writing is less expository and more evocative.

Some critical curriculum theorists regard postmodern historiography as nihilistic because it dismantles truths without offering any replacement truths. At the same time, critical and effective histories do not usually claim that there is no such thing as truth; rather, postmodern historiography raises the possibility that historical inquiry may have worthwhile educational purposes other than the search for truth. For example, postmodern historiography may pursue justice, cultivate aesthetic pleasure, generate moral values, explore uncharted intellectual territory, or awake a human spirit. For proponents of postmodern historiography, the critical value of the postmodern approach is that it expands historical inquiry beyond the search for truth, thereby undermining the basis on which dominant knowledge has become exclusive and limiting.

In general, postmodern historiography is critical and provocative rather than realistic or explanatory. By implication, postmodern historiography has posed challenges to curriculum studies. For example, from the perspective of postmodern historiography, curriculum history can be evaluated on the basis of its methodological rigor and fidelity to established facts and on the basis of its political effects, literary merit, and the degree to which the history generates critical thinking or provokes political activism. The shift of purpose from truth-seeking to critique also contributes to curriculum theories that seek to explain various mechanisms of knowledge production. For example, in curriculum theory, postmodern historiography pushes definitions of knowledge to extend beyond the realms of science and cognition, and into realms of literature, aesthetics, ethics, politics, and power.

### Focus of Study

Postmodern historiography differs from modern historical inquiry in its focus of study. Postmodern historical studies tend to focus on the local and particular, in contrast to modern historiography that tends to focus on the general or universal. Postmodern historiography emphasizes differentiation, discontinuity, and minority viewpoints, in contrast to modern historical inquiry that seeks to establish general patterns, overall similarities, and dominant trends. Because the focus of study is the particular and local, postmodern historiography places more emphasis on uniqueness, deviation, and individuality in history; relatively little historiographical importance is granted to generalizability, normality, and statistical models of regularity and prediction.

Tending to focus on the particular and to emphasize differences, postmodern historiography has provided a venue for histories of many marginalized groups and unrecognized perspectives. One example of this focus can be found in postcolonial histories, notably those written from the perspective of people from former colonies in Africa and the Asian subcontinent. Postmodern historiography generally works against modern tendencies to establish universal or comprehensive theories of history. Because of its focus on the local and particular, postcolonial historiography has extended the scope and focus of curriculum studies to include languages, ways of seeing, cultural sensibilities, and political nuances that had been disregarded or placed outside the realm of modern historiography.

### Epistemological Commitments

In general, modern historiography is characterized by an epistemological stance of scientific interpretation, discovery, or sense making. In contrast, postmodern historiography enacts epistemological commitments that are less fixed and more contingent on context and power relations. Some postmodern historiography can be regarded as interpretive, however, the interpretation may not aspire to approximate the truth as much as it strives to stimulate critical questioning and awaken fresh perspectives. Postmodern historiography

usually resembles invention and narrative more than discovery or recording. In addition, postmodern historiography has a complicated relationship to epistemologies of social constructivism. Some theories of social constructivism claim that truths are constructed through democratic and collective discourse; other forms of social constructivism claim that people construct their own unique paths to the truth. Various versions of social constructivism may or may not be regarded as postmodern, depending on which variety of postmodernism is espoused.

Representation is a crucial epistemological issue for postmodern historiography, just as it is for curriculum theories. In its departure from structuralism and realism, postmodern historiography rejects the assumption that history can be or should be a representation of the past. For modern historians in general, language represents reality, and from a modern perspective, it is possible to separate what happened in history from the historical record that has been written about what happened. However, in postmodern historiography, it is difficult or impossible to establish an ontological or epistemological difference between history and what we write about it. From the standpoint of postmodern historiography, history is precisely what we write and say about it. Most careful historians of any stripe acknowledge that history is always written from a particular perspective. Recognizing the inevitability of selective perception in history, postmodern historiographies are unapologetically perspectival, and they generally make no pretense toward objectivity or neutrality.

Concerning curricular theories of knowledge production, the relationship between empiricism and postmodern historiography is also complicated. If empiricism is understood as some kind of objectivity, then postmodern historiography is nonempiricist because it rejects claims to a neutral point of view and unmediated realism. However, postmodern historiography is usually also post-structural. In its rejection of structuralism, postmodern historiography focuses on perceptible phenomena rather than on underlying structural abstractions. Because postmodern historiography calls attention to worldly practices, in that sense it can be regarded as empiricist.

As a mode of inquiry that is more critical than truth-seeking, postmodern historiography is generally more closely related to literary studies than to social sciences. An influential example of this relationship can be found in White's work, especially in his historiographical position that analyzes history in terms of literary tropes such as tragedy, irony, and heroic myth. White's contributions to historiography have been mobilized in curriculum theories to challenge theories of knowledge production that are exclusively scientific, positivistic, or realistic. Postmodern historiographical approaches make it possible to regard knowledge as discourse and history as narrative.

## POSTMODERNISM

---

Postmodernism can be viewed not so much as an "ism" (which suggests something complete, totalized, unified) as a social, discursive, cultural, and political turn—a turnout of and away from the modern, from previously customary modes of thinking and living. Some argue that this turn was precipitated, in great part, by sociopolitical movements during the 1960s in the West, particularly theorized by French philosophers, historians, and linguists, that resisted and attempted to overthrow normalizing and often oppressive social mores,

structures, and practices. Such a turn became apparent in the 1970s and 1980s through a proliferation of new media, technologies, mass cultures, reconceivings of capitalism, consumer and information societies, urbanization, and cultural forms that questioned modernist Enlightenment ideals of rational, fully conscious humans and the quest for foundations on which to base claims of eternal truth and certainty.

The postmodern turn was evidenced most dramatically within U.S. curriculum studies during the 1970s and 1980s with the move by a group of theoretically diverse scholars to "reconceptualize" the field's technical-rational focus and prescriptive and managerial nature to encompass efforts to "understand" curriculum. Drawing on the Latin word *currere*, to run—as in running the course of a race—reconceptualized curriculum involved attention to processes of inward journeys to explore experiencings of educative activities as well as to examine larger social and cultural contexts and power relations that framed such experiencing. Reconceptually oriented curriculum scholars introduced psychosocial, humanities-based perspectives as well as neo-Marxist political analyses in response to the deficiencies of conceiving of curriculum and its design and development as another version of "truth and certainty"—as linear, sequential, predictable, and measurable versions of supposedly universally agreed-upon versions of content as well as pedagogical and learning processes.

#### Descriptions of the Postmodern From a Variety of Disciplinary Perspectives

One primary way of considering the "postmodern turn," however, is not so much a particular moment in chronological time but as more a moment in logic, or a rupture—a break—in modernist consciousness. The "postmodern" cannot be considered only in linear configurations, as in limiting the term to a stage following modernism. At the same time, the language of the burst in modernist consciousness must mention and call into question its antecedent before attempting to move into projects that interrogate the processes of naming, claiming, and representing.

That antecedent, modernism, was instilled by René Descartes's claims for the supremacy of

reason in discovering the truth about a rational universe; by Francis Bacon, John Locke, and Thomas Hobbes, who argued that reason be supplemented with experience in making knowledge claims; by Immanuel Kant, who developed theories of knowledge, of what is morally good, of beauty and the sublime—all based on reason and a conception of the mind as an active, organizing synthesizer of innate mental categories of sense experience.

In contrast, “postmodern(ism)” can be considered as an awareness of *being-within* a particular way of thinking, language, and a particular cultural, social, historical framework. Simultaneously, one irony of considering postmodernism as such is that one never can fully name the terms of this way of thinking. “Naming” assumes the one who names as being outside of a moment as well as outside language. From postmodern assumptions, however, there is no being “outside” of history or language and discursive constructions of identities and experiences from which to “objectively” name the present.

Further, Jean-François Lyotard, the French philosopher, argued that “the postmodern condition” triggered disbelief toward metanarratives, toward large-scale theories and philosophies of the world—such as the Western belief in linear time and the progress of history. Such grand stories offer explanations that attempt to make sense of the world through one universalized, totalized, overarching truth, based on foundationalism and essentialism. In contrast, postmodernism values local, contingent truths and identities; notes how reified versions of knowledge position subjects within certain discourses by enabling particular possibilities and repressing others; and focuses on issues and discursive constructions of difference.

Postmodernism, too, is a contradictory phenomenon, one that sets up and then subverts, that uses and exploits, the very concepts it challenges—be it in music, film, architecture, painting, literature, historiography sculpture, video, dance, TV, philosophy, aesthetic theory, psychoanalysis, or linguistics. Postmodernism questions all absolutes; juxtaposes high with popular culture; raids and parodies past art; peppers cultures with recycled, simulated, and replicated images—copies without originals. Postmodernism is not divorced from everyday

life, but is of it. Distinctions between “high” and “popular,” “secular” and “religious,” “past” and “present” are challenged and disrupted to think of the world in different ways, where hierarchies are not generated by universal transcendent values but by the ideologies and discourses that enable/persuade people to understand the world in particular terms and worldviews.

For example, much modernist fiction has a paradoxical aesthetic unity, as though art could contain life’s chaos and create an order, as in Henry James’s modernist pattern of the form and artistry of literature. Postmodernist writing frequently mocks this pretension to pursue order through language, and often instead is parodic, playful, carnivalesque, showing language breaking down or falling into exaggeration and aesthetics as reduced to spectacle. There are no immutable standards of judgment, only, as Roland Barthes notes, pleasurable responses to the spectacle.

Further, the assumption of a creative author/subject who gives a literary work its meaning is radically disrupted in postmodernism; rather, as Barthes and Jacques Derrida note, it is language that speaks the work, not the author. Meanings are constantly deferred; authors continuously are borrowing and alluding. Postmodern texts play with the idea that thought is basically linguistic, and often do this in open and subversive ways. Relatedly, the concept of intertextuality, coined by feminist theorist Julia Kristeva whose realm is that of semiotics, refers to how one or more systems of signs are transposed into another, resulting in a chain of differential references—the intertexts of a text.

Consequently, terms of intertextuality figure prominently in discussions of postmodernism: parody, copy, plagiarism, pastiche, palimpsest, simulation. In another example, “postmodern novels” both insert themselves self-reflexively in history, often blending fictional characters and real events, and also self-consciously discussing or alluding to the conditions of their own narration.

Conceptualizing postmodernism, then, is problematic, given that any attempted formulation must immediately involve a constant questioning of presumptions underlying the very conceptual efforts themselves as well as the discourses available to even challenge and interrogate.

### Influences on and Implications for Curriculum Studies

A number of curriculum scholars have been influential in the curriculum studies field through their illuminations of why educators necessarily must take into account the questions and inquiries that the postmodern poses. These scholars urge curriculum studies scholars/practitioners to question the field's grand narratives, its essentialist and foundationalist beliefs, and taken-for-granted and habitually conditioned assumptions. They also argue that postmodern conceptions reject versions of curriculum as a linear and insular field of design and development of predetermined and measurable content. They instead point to implications for curriculum of time as losing its neat linearity, cultural spaces as expanding, contracting, constantly morphing, and boundaries of disciplines, schools of thought, and methodologies as losing their stiff demarcations in favor of fluid, permeable, membranous contingencies.

Thus, postmodern influences point to a consideration of curriculum as involving attempts to understand what and how in- and out-of-school, conscious and unconscious curriculum choices and predispositions might mean differently in varying contexts and discursive constructions, and through the eyes of multiply positioned educators and students. Postmodern versions of curriculum studies have pointed to necessary examinations of the variety of discourses that posit certain meanings as well as subjectivities—and not others—as desirable in educative processes and encounters. And, in its decentering of the humanist subject, its challenging of any claims of full representation of self and others, and its insistence on plurality and on conceptions of difference that do not automatically work toward “sameness,” postmodernism encourages fresh conceptions of curriculum, ones that acknowledge complexities, contradictions, paradoxes, and unpredictable networks of relationships and ideas. Such versions of curriculum always will be in process, always subject to revisions, always in-the-making.

Postmodernism thus enables educators to view curriculum as both processes and content forever in flux and subject to multiple interpretations. Such conceptions acknowledge that all educators and students are involved with and in complex

interactions that may be classroom-based, but that are inflected with often competing discourses as well as differing and yet often normative social and cultural versions of “good teacher or student,” or what and who counts as knowledge worth knowing, for example.

Further, even when curriculum “must” be considered as “content” in relation to mandated accountability and achievement test scores, for example, postmodern perspectives enable educators to note that what contains also excludes. What appear to be universally accepted norms for subject matter content as well as “best” pedagogical practices are maintained in their apparent unity only through an active process of exclusion and hierarchies. Some postmodern curriculum theorists, for example, have examined social systems in education by paying close attention to constructions of margins, borderlands, and “outsiders” to highlight how positions of hierarchical power in individual and social configurations can only function through repression of the other.

From another perspective, William Doll takes up a postmodern worldview based on quantum physics, nonlinear mathematics, general systems theory, and Ilya Prigogine's nonequilibrium thermodynamics. As first evidenced in his work within the reconceptualization of the curriculum field, Doll does so to counter a Newtonian worldview, which is linear and reductionist. Doll describes the theoretical foundation of Ralph Tyler's notions of an orderly, linear, and sequential development of curriculum with ends preset, and of B. F. Skinner's conceptions of expressing learning in discrete and quantifiable units.

Doll argues that these conceptions assume the whole to be no more than the sum of the parts, and lead to a curriculum that is cumulative rather than transformative. He posits that Prigogine's notion of nonequilibrium in the process of becoming is a more accurate model for a curriculum than is Isaac Newton's physical, inert, mechanical structures. In particular, Doll argues that curricula should be structured as self-regulating “open systems” where internal, autocatalytic transformations are encouraged. To move from a curriculum based on the simple and separate to one based on the complex requires educators to adopt a radically new relationship with students and a more integrative approach to subject matter. A postmodern curriculum,

for Doll, will be transformative rather than incremental with respect to change, will accept students' ability to organize, construct, and structure, and will emphasize this ability as a focal point in the curriculum.

Patrick Slattery addresses the very notion of curriculum development—a modernist, technical-rational concept, according to most postmodern critiques—to take a sweeping view of the need to understand curriculum in relation to global religions, ethnic relations, multicultural communities, and sociopolitical interest groups. By situating his postmodern analyses of how curriculum “development” might be reconceived within a new public discourse for justice, Slattery posits that a visceral response to disequilibrium provoked by the postmodern turn can be generative in terms of directly dealing with contentious contemporary issues such as discursive and material constructions of gender roles and sexual orientation, academic freedom, ethnicities, and religion and prayer in schools. And in offering a range of postmodern perspectives and analyses in relation to interpretive processes, multiculturalisms, ecological sustainability, time and complexity, and aesthetic inquiry, Slattery demonstrates ways in which curriculum development within the postmodern must be approached from autobiographical, historical, socially, culturally, and discursively contextualized perspectives and goals—and then immediately questioned.

The postmodern condition, the turn, the moment(s)—however impossible it may be to sum up, there is nothing about postmodernism that enables a simple mapping of theory onto practice to reach any final version or closure. Postmodernism has influenced the contemporary field of curriculum studies by pointing to ways in which any version of curriculum and curriculum studies is an interpretation and thus a will to power, to dominate. Important implications of the postmodern for conceptions of curriculum and curriculum studies thus are found in its calls for caution, responsibility, and self-reflexiveness in searching for gaps, contradictions, and silences in one's own interpretations, and in making room for competing and contrary interpretations. These implications can be seen as gestures toward openness, toward creating spaces that enable particular awarenesses as well as interrogations, and toward potentials for diversity of thoughts and constructions of subjectivities that

resist positioning any one idea or person as permanently “other.”

## POST-RECONCEPTUALIZATION

---

Post-reconceptualization raises questions about the state of the field of curriculum studies after the reconceptualization movement of the 1970s. More specific, the term gained significance after a 2006 conference entitled “Articulating the (Present) Next Moments in Curriculum Studies: The Post-Reconceptualization Generation(s),” which focused on exploring contemporary scholarship within the field. What has become evident both at this conference and in journal articles and essays where the term *post-reconceptualization* is used is that although the reconceptualization movement has passed—and what remains are debates about its significance—post-reconceptualization is itself a site of debate and contestation because it is still under formation. Accordingly, the remainder of this entry is focused on various perspectives that have been developed thus far to describe post-reconceptualization.

The first perspective is focused on a generational change and in the scholars who make up the field and how events of a particular time period shape scholarly outlooks. Here, what has been written about involves the challenges that mark the reconceptualization and post-reconceptualization movements and scholars' reactions to them. During the initial reconceptualization of curriculum studies, scholars were reacting to the governmental intrusion of the 1950s and 1960s into curriculum issues under the rationale of economic competitiveness and national security. Citing *Sputnik* and the need to advance technology and science to compete with the former Soviet Union, policy makers became more central than curriculum scholars to conceptualizing school content. Scholars of the reconceptualization movement challenged their lessening authority in regards to school curriculum matters as well as the general institutional and bureaucratic nature of curriculum thought. During this post-reconceptualization moment, a new generation of curriculum scholars reacts to the continued imposition of government within curriculum matters, particularly with the No Child Left Behind Act, but with a more robust theoretical tradition from which to draw in conducting inquiry and analysis, due in no small part to the reconceptualization movement. Regarding this first perspective, post-reconceptualization has to do with the challenges that confront a new generation involving current events and available theories and their reactions to them.

The second perspective is attentive to a new phase in curriculum theorizing. Here, what has become evident is that the post-reconceptualization generation is producing scholarship in new and unforeseen ways. Some scholars are drawing together various discourses evident in the reconceptualization movement to craft their own hybrid orientations. This includes holding together seemingly incompatible ideas, such as those borrowed from queer theory and personal narrative or critical race theory and autobiography. Other scholars are continuing the tradition of importing theories and ideas from other fields to complicate the nature of curriculum scholarship. Some of these other bodies include critical geography, existential philosophy, and cultural studies. Still other scholars focus on reconfiguring existing curricular concepts to shed new light on familiar topics. Some of

these reconfigurations include a shift in focus from poverty to privilege and reconfiguring notions of space so as not to signify emptiness but places of relations and proximities. A few scholars are taking the ideas and concepts of the reconceptualization movement as a paradigm shift and exporting them to other fields to incite an intellectual reorientation. The disciplines of export in this process include math and art education. A select group has also concentrated on understudied and unstudied histories within the curriculum field. Here the focus is on rereading practices that shed new light on historical figures and concepts that have become important to the field. Lastly, some continue to attend to state of the field questions, but do so with a focus on multiplicity and proliferation rather than reduction to key principles and centers of curriculum scholarship.

Finally, a third perspective is focused on extending beyond the notion of paradigm shifts to think about advancement in the field in new and different ways. One approach has involved a focus not on new theories and ideas but on translations across differences or clusters of theorizing within the field. Here, the idea is not to create new theories but figure out how to make meaning across differences. The idea is to develop through-lines across clusters of theories that are seemingly incompatible to strengthen the network of relationships that make up the field. Another involves attention to the ways extant theories and ideas can be reinvented by way of new metaphors and frames of reference. Here, the idea is to find vitality in existing theories and ideas when new ideas are brought to bear on familiar ideas.

In contrast to the conservatism that has surfaced in the form of standardized national curriculum, post-reconceptualization is about multiple novel and creative ways for going about studies in teaching and learning. If the scholarship that has been associated with the term *post-reconceptualization* is any indication, curriculum scholars are confronted with two tasks. The first is finding ways to continue with curriculum theorizing in the face of the demise of traditional knowledge centers, the dissolution brought on by postmodernism and poststructuralism. The second, quite ironically, involves finding ways to continue given the rise of new orthodoxies in what will be recognized as valid educational research and curriculum

concepts. Curriculum scholars have approached these tasks through postempirical work that assumes the ground for human knowledge is neither rock solid nor unquestionable but rather conjectural and uncertain. Also, they have approached these tasks through reading practices that attempt to intervene within discourse to change what is thought about when one thinks about curriculum. As a concluding thought, it is important to acknowledge that post-reconceptualization is a relatively new idea. Whereas it will one day become a part of curriculum history, to be studied for its significance, it is currently under formation. That is, it is a site of debate and sign of vitality within curriculum studies.

## POSTSECONDARY CURRICULUM

---

The postsecondary curriculum in the United States refers to the educational and academic courses of study offered by a variety of institutions, anchored by colleges and universities and extending to include community colleges, junior colleges, technical institutes, professional schools of law and medicine, seminaries, and academies. For U.S. colleges and universities and these related institutions at the start of the 21st century, the postsecondary curriculum exhibits a highly standardized structure, format, and lexicon. Across the expanse of more than 2,000 degree-granting institutions, which annually enroll more than 14 million students, there is consistent usage of such formal components as “major field of study,” “minor field of study,” “general education requirements,” “distribution requirements,” and “elective courses” as part of academic degrees. These terms also are homogeneous across institutions in the accounting

system of “units of credit” and calculations of “grade point average.” Whereas in England’s historic universities of Oxford and Cambridge, instruction in residential colleges is separated from the examinations and conferral of degrees by the central university, in the United States, virtually all institutions have settled on a practice in which faculty who instruct students in courses also formally evaluate student work and assign numerical grades for academic credit—and, subsequently, make decisions on student degree completion.

Furthermore, most institutions have distinct units named for curricular areas. The “College of Arts and Sciences,” “College of Engineering,” “College of Medicine,” “School of Architecture,” and “Graduate School” stake out subject matters. Within each academic unit, areas of study are subdivided into departments—ranging from astronomy to zoology. A small number of institutions depart from these conventions—but apart from these important exceptions, the standardization of the structure of the courses of study is remarkable in its homogeneity. One reason for this is ease of interinstitutional cooperation in making decisions about student transfers along with admissions decisions between undergraduate and graduate levels of study—along with demonstrating eligibility for federal student aid programs. This uniform structural façade, albeit important, tends to mask the lively and diverse deliberations about institutional mission, educational philosophy, budget allocations, and debates about what is to be studied and how it is to be taught in recent years.

### Development of Contemporary Postsecondary Curriculum

The hegemony of this academic structure has not been inevitable. Between 1965 and 1980, a number of academic leaders argued that reform of undergraduate education required rejection of conventional practices of institutional structure, grading, and size. For example, one slogan that united discontented undergraduates in the 1960s was that the “impersonality of the multiversity” had tended to denigrate undergraduate education by conveniently relying on large lecture courses and impersonal multiple-choice examinations in which professors and students had little conversation. Remedies included developing small undergraduate

courses, shifting seminar instruction from graduate programs to undergraduate programs. More drastic were innovations associated with the “cluster college” movement of the 1960s. Foremost in this category and energy was the new University of California, Santa Cruz—an experiment hailed as the solution to the riddle posed by Clark Kerr: “How do we make the university seem smaller as it grows larger?” The answer pursued by the University of California, Santa Cruz, and others was to find inspiration in the Oxford-Cambridge model of residential colleges. According to this plan, the curriculum came to be comprehensive: an architectural environment of a quadrangle in which living and learning, students and faculty, were brought together in a humane scale, limited to about 500 or so total students per college. Additional students were to be accommodated by adding new, small residential colleges—resulting in a honeycombed pattern of universitywide expansion. Instructors were to provide written commentaries for each student’s academic performance in place of the standard practice of assigning a letter grade or numerical score. Eventually such plans encountered problems: First, residential education and small courses were expensive. Second, many undergraduates were reluctant to sacrifice all the curricular and extracurricular choices of the large, sprawling university to gain a small, coherent residential collegiate experience. Third, most students did not relish the responsibility of designing their own course of study, especially if such a task demanded the discipline of building in coherence as well as choice. By default, familiar and conventional curricula were less demanding and more certain. Most important, the “cluster college” scheme faced difficulties in gaining acceptance of faculty at universities where rewards and prestige often were tied to achievements in research publications and grants, with less emphasis on commitment to undergraduate teaching and mentoring.

Therefore, pervasive contemporary reforms in postsecondary curricula take place within the conventional structure. The tradition of departments continues—but the innovations of new fields gaining departmental status represented a substantial change. Undergraduates were allowed to pursue independent studies and even to create their own major. A variety of options, ranging from honors seminars to special topic courses, incorporated some elements of the “cluster college” idea to the

conventional academic structure. In subject matter, “area studies” flourished to accommodate interdisciplinary and multidisciplinary cooperation in, for example, “American Studies,” “Asian Studies,” “Environmental Studies,” “Ethnic Studies,” ad infinitum. Whether such collaborations endured or perished varied from campus to campus, from topic to topic.

### Curricular Contraction

Although growth by accretion characterized postsecondary curricular patterns in the half century following World War II, there also were varied means and signs of curricular contraction. A watchword in the financially troubled years of the 1970s was “steady state growth.” This meant that a provost would not allow a dean to add new departments or programs unless equal shares of incumbent programs were eliminated. The net result was a constant number of academic programs. Departmental closings and mergers were part of the economies of scale and retrenchment that were integral to attempts at systematic academic planning starting in the mid-1970s. Today, from time to time, one learns that major universities have eliminated departments of German, Italian, and Rhetoric. Ancient languages including Greek and Latin—once pillars of liberal arts curricula—have declined and often survive in reconstituted forms via mergers and consolidation into new units called “Classical Studies.” Even high-profile professional schools are subject to scrutiny. Most conspicuous is the closing of several schools of dentistry, justified on the grounds that the programs are expensive to operate and that the market for graduates has been saturated.

### Criticisms of the Undergraduate Curriculum

Even though existing academic structures may have been intractable, there has been no lack of spirited reconsideration of the content and goals of undergraduate education. Volatile discussions in the public forum and national media as well as within departmental meetings have characterized curriculum trends in the humanities and social and behavioral sciences since the early 1980s. Precipitated by such books as Allan Bloom’s *The Closing of the American Mind* along with the

criticisms of undergraduate studies by then-U.S. Secretary of Education William J. Bennett, faculty in departments of history, English, sociology, and government have been prompted to deal with allegations that teaching perspectives have drifted toward an orthodoxy of “political correctness.” A distinct but related criticism is that the fluid structure of curricula have allowed many colleges and universities to allow a proliferation of courses and programs so that the principle of a shared educational experience or common body of knowledge associated with the undergraduate experience and the bachelor’s degree has been fractured and diffused. The subtext of this general lament often has carried the more specific criticism that political correctness combined with overexpansion of courses led to the neglect and erosion of what is termed the “Western Judean Christian heritage.”

Responses to these criticisms of curricular change are diverse and multiple. One prominent counterargument is that the academic disciplines ought to be introduced to students less as a body of knowledge to be mastered and more as a set of essential concepts and ways of knowing which, once understood, a student then incorporates into subsequent interpretations of readings and intellectual explorations. Another, perhaps more vehement response, has been that the curriculum in the arts and sciences ought to present undergraduates with topics, readings, and points of view that deliberately step outside the more-or-less conventional, familiar social, political, philosophical, and religious groundings of U.S. life. This impulse for expansion and diversification were manifest in the founding (and funding) of new departments of African American studies, women’s studies, and gender studies.

### Curricular Expansion

An irony of the intense popular and academic focus on what was called the “canon” debates and “curricular wars” in the liberal arts was that elsewhere within a typical university, curricula underwent substantial changes without debate or controversy. Illustrative of this quiet transformation was the evolution and formalization of such new disciplines as computer science. Statistics, once considered a support field, emerged not only as a distinct department—it often gained repeated

presence as each academic college or school added its own statistics faculty. In the natural and physical sciences, new alliances led to creation of interdisciplinary research institutes and, eventually, the creation of such new, permanent departments as biochemistry, biostatistics, and biomechanics. One corollary was that university medical centers increasingly became the institutional home for numerous biology degree programs. The attractiveness of these new courses of study was largely fueled by the prevalence of sponsored research and development funding via grants from federal agencies. In sum, the sponsored research agenda often drives the instructional dimensions of the curricula—whereas in an earlier era, the reverse pattern was the norm.

Institutional pursuit of prestige provides another impetus to curricular expansion: namely, “mission creep.” The pattern is that an institution that offers only a bachelor’s degree decides to “ratchet up” by adding a new master’s degree program. In similar fashion, comprehensive universities traditionally characterized by offering bachelor and master’s degrees often venture into proposals to offer new doctoral programs. This curricular drift upward was fueled unwittingly by the Carnegie Council on Higher Education Policy Studies’ announcement in the 1970s of a typology for U.S. postsecondary institutions. The format ostensibly was intended to be a neutral categorization of the numerous colleges and universities according to their highest degree conferred. Yet within the ranks of presidents, provosts, and professors, it was perceived as a hierarchical ranking. Hence, for an institution to be in the doctoral granting category was seen as more prestigious than the master’s degree granting category.

Curricular growth as a function of the expanding “knowledge industry” is not the only consequence. Curricular growth also has promoted an internal change within academic units: namely, the intensification of splits and rivalries within academic fields. A department of political science, for example, increasingly would be characterized by analytic and emotional tensions between those emphasizing statistical analyses versus faculty who favored contextual or area studies.

A substantial increase in the number and percentage of high school graduates who were willing and able to enroll in undergraduate programs after

1970 was accompanied by the upward drift of enrollments into degree programs beyond the bachelor's degree. Most prestige and attention accrued to the pinnacle of the academic curriculum: namely, advanced studies leading to the PhD in a growing number of fields. Less conspicuous but also important was the growing appeal of master's degree programs. The size, scope, and number of the MBA programs nationwide best illustrate this trend. The incentive for a student to gain expertise and credentials, and perhaps prestige, also tended to drive the appeal of master's programs in most disciplines associated with the liberal arts along with professional fields, including education, social work, and engineering. A substantial change has been in health-related fields, as advanced degree programs in nursing, physical therapy, and counseling experienced quantitative and qualitative change. Trends in the health-related fields were mirrored elsewhere as a growing number of professional fields sought to establish certification and degree programs offered by colleges and universities. The increase in professional fields of study were attractive to two influential constituencies: students and their parents who wanted the bachelor's degree to ensure employability, and employers who wanted recruits whose formal studies entered the professional ranks with job skills and even advanced certification. The irony of these influences was that they were not fail-safe for either students or employers. One economist, after analyzing the uncertainties of connections between campus and corporation, warned that the U.S. public and academia had been overzealous in embracing what was called "The Great Training Robbery."

### Fusion of Curriculum and Extracurriculum

Within the diversity and sprawl of postsecondary curricula, there persists one litmus of academic legitimacy: namely, does instruction or study or other activities associated with a topic result in a student receiving "academic credit"? Course credit and credit toward completion of a degree persists as the coin of the academic realm. Indeed, at many colleges and universities, reserving this decision exclusively by the faculty emerges as the major power of the professoriate within myriad

institutional rights and responsibilities. The boundaries of the postsecondary curriculum now are tested and contested by a new logic that, ironically, was fostered unwittingly by academics themselves. The customary wisdom was that the curriculum was indelibly linked to the instruction and evaluation under the auspices of the college or university faculty. At the same time, advocates for the benefits of going to college, ranging from presidents to professors, often emphasized that a student's experiences outside the classroom were, too, invaluable albeit unmeasured parts of a college education. Ultimately this led some deans of students or vice presidents of student affairs to describe (and justify) their myriad programs less as "extracurricular" activities—and more as "co-curricular" in nature. These both joined and blurred the strictly academic domain with student life writ large. A good example of this new ground came in the early 1990s as students took the initiative to create service learning activities. A subsequent juncture was when students petitioned the faculty and academic senate to have the activities eligible for receipt of academic credit toward the degree. Resolution of this and comparable initiatives has varied greatly from one faculty group to another.

Systematic evaluation of cognitive and behavioral profiles of students now is part of the fusion of curriculum and extracurriculum. Although course grades ranging from A to F—or the 4.0-point grade scale—is central to academic evaluation, the rise of psychological testing amended this by shifting to value added data for students. Evaluations were part of a demand for "accountability" in which legislators sought measures of the impact of the college experience. It includes accountability for instructors with the practice of students evaluating courses at the end of the semester. The origin of this was administrative initiative to document shoddy teaching. The unexpected finding was that students gave high evaluations to instructors—opposite of what administrators anticipated. The practice reinforced the importance of student consumerism in the U.S. academic market place. And, as a corollary, this increased disagreement about what constituted a sound college education.

## POSTSECONDARY CURRICULUM, HISTORY OF

---

The history of postsecondary curriculum in the United States refers to the continuities and changes in the formal courses of study offered by colleges and universities and numerous related educational institutions from 1636 to the present. Over five centuries, it has been characterized both by rigidity and resilience. A central part of the story is the requirements and options students face in completing the undergraduate bachelor's degree. On closer inspection, the richness of the curriculum—or, more accurately, the curricula—in U.S. higher education has been the number and variety of professional and advanced degrees, such as the MD, the MBA, the JD, the MA, and the PhD conferred by colleges and universities. And, since 1960, community colleges' 2-year associates' degree programs have become integral to the

national curricular profile. An obvious but incomplete source of historical information is the official catalogue of courses typically published by each institution annually. However, a complete conceptualization of the postsecondary curricula is to see the official course requirements and listings as the skeleton, which then is fleshed out by the actual teaching and learning that took place within this formal structure over time.

The rigidity of the typical collegiate course of study from the late 18th through the 19th centuries is illustrated by the endurance of a “classical course” to define a liberal arts education. It emphasized daily recitations in ancient languages, logic, rhetoric, and mathematics—as affirmed by the Yale Report of 1828. This collegiate pedagogy aimed to have undergraduates acquire the “furniture of the mind.” In contrast, the resilience and expansion of the postsecondary curricula in U.S. colleges and universities was best expressed in the motto attributed to the benefactor of the new Cornell University in the 1860s: “I would found an institution where any one could find instruction in any study.” The resulting dynamic has been a continual push-and-pull of action and reaction, often debated in faculty meetings across the country and ultimately resolved by the enrollment choices of new generations of students.

The absence of a centralized national ministry of education in the United States allowed each institution to add or delete subjects and courses. So, although by custom and inertia, most colleges offered similar topics in the bachelor of arts course of study into the early 20th century, one also finds on the margins a proliferation of innovations—both within and across institutions. Innovation often gravitated toward demands for utilitarian studies. Hence, one finds an increasing number of options, including “scientific schools” and its bachelor of sciences degree, or a liberal arts course that no longer required classical languages, leading to the new PhB, or “bachelor of philosophy” degree.

Since the early 20th century, the greatest source of innovation and diversification has been in the addition of new professional fields and advanced degrees. Absorption of medicine and law into the university degree structure, including coordination with the undergraduate studies and prerequisites,

was an exemplary development. Universities also added such new professional fields as agriculture, forestry, business, teacher education, and engineering. Many applied fields gained sustained support from the 1862 Morrill Act and subsequent federal legislation. The social and behavioral science disciplines of political science, economics, history, sociology, psychology, and anthropology were daring innovations in the late 19th century. Romance languages along with English and U.S. literature also signaled a revision of what constituted the arts and sciences core of the university. In recent decades, the development of such new fields as statistics, computer science, women's studies, African American studies, and biochemistry has extended this curricular process.

The U.S. tradition of generous license for curricular development fostered from time to time a countermovement to instill some approximation of national "standards" and "standardization." Illustrative of this effort was the Carnegie Foundation for the Advancement of Teaching's agenda in the 1900s, which relied on incentive of a funded faculty pension plan for those institutions that agreed to comply with new standards for secondary and collegiate course accountability. Following World War II, responsibility for trying to ensure minimal standards of curricular legitimacy became the province of regional accreditation agencies.

Starting in the late 19th century, introduction of an elective system coupled with requirements for a major field and a minor field provided undergraduates a new set of ground rules for designing their courses of study. One result of this freedom and student consumerism was that by 1960, academic leaders spoke about the "cafeteria line" model of U.S. higher education. This U.S. compromise included both the strengths and weaknesses of relativism—leaving to adult decision makers and student applicants the subtle tasks of evaluating the academic worth of degrees and courses within this broad framework. One secondary consequence of this format was recognition of a so-called hidden curriculum in which students were socialized to acquire informal skills at navigating the course of study and deciphering the kinds of learning and academic socialization that were rewarded by their respective professors.

Historical emphasis on the cumulative names of fields and degrees attests to the expanding subject

matter offered by institutions. Also, numerous transformations in instruction accompanied new fields. Hence, the standard format of daily recitations came to be supplemented by lectures (with the professor as expert), access to a library plus seminars, laboratory sessions, field studies, independent research, internships, honors programs, and senior research theses. It has included correspondence courses in the late 19th century, televised instruction in the 1950s, and distance education interactive pedagogy associated since the late 20th century with the Internet. The structural beauty of the U.S. course catalogue was that it was able to accommodate each and all subjects and teaching approaches into a standardized manner, complete with assigning credits toward degree fulfillment. As for the substance within these frameworks, the U.S. curricular motto remains, "caveat emptor"!

## POSTSTRUCTURALIST RESEARCH

---

Curriculum poststructuralist researchers assume that varied conceptions of what and who shapes and constitutes curriculum are embedded in and

enacted through historically, socially, and culturally situated discursive practices and constructions. Poststructuralist research focuses on the local, the fragmented, the ambivalent in knowledge creations as well as research processes and interpretations. Poststructuralist researchers acknowledge contradictions and instabilities in all assemblages of human knowledge, most especially their own. They especially consider under what historical, social, and cultural conditions particular discourses—and those who have most direct access and power in relation to those discourses—come to shape what gets conceived, built, and enacted as curriculum. This entry discusses the general foundations of poststructuralist investigation, examines the poststructuralist theories that inform curriculum studies, and provides examples of poststructuralist research in curriculum studies.

### Foundations of Poststructuralist Investigation

These curriculum researchers challenge what Jean-François Lyotard would term a “grand narrative”—an ultimate, decontextualized, universalized way of conceiving, constructing, and conducting any curriculum inquiry, conception, content, design, development, or evaluation. Poststructuralists research such curriculum narratives by investigating ways that meanings, “content,” experiences, and selves are, in part, discursively constituted—that is, they “exist” in, rather than outside, language. The self and its objects of perception are effects of a language that always is in process, always modifying itself.

Refusing unitary positivist educational research ideals of rationality, causal explanations, and generalizations, then, these researchers denaturalize and destabilize what seems “natural” as well as interrupt essentialized educational thought, practices, and identities. They investigate how, and under what conditions, particular discourses—what Michel Foucault refers to as written or spoken words that are grouped according to certain rules established within those discourses—come to shape what gets put forth as knowledge, who counts as being able to generate knowledge, and what shifting power relations influence and frame any one curriculum or research interpretation.

Specifically addressing issues of power, poststructuralist researchers examine not only what and whose determinations and creations of knowledge count but also how those creations are produced, how they function, and how they are regulated as well as regulate. Poststructuralist curriculum researchers often investigate what cultural and social practices, embedded in and constructed by particular discourses, constitute, replicate, or call into question subject-matter content—or what many educators often generically refer to as “the curriculum.” They also might research social and cultural effects of particular versions and conditions of curriculum constructions and practices on students, teachers, administrators, and parents. And because these researchers doubt the ability of language as well as themselves to perfectly report an external reality, or to convey an ultimate meaning about events, people, or conditions framed by that particular reality, they grapple throughout their inquiries and writing with the crisis in representation.

Influenced by scholarship in literary theory, the arts, philosophy, anthropology, architecture, linguistic and cultural studies, and in the name of various political agendas, including feminism and postcolonialism, poststructuralist curriculum researchers attempt to work in generative ways with, rather than against, the complexities of human existence. They attempt to trouble various reductionisms that are an inherent part of traditional curriculum conceptions as well as positivist and postpositivist educational research paradigms. At the same time, others, many working from critical neo-Marxist positions in curriculum theorizing, argue that a central tenet of poststructuralist theories—that there can only be incredulity toward metanarratives—is itself a grand narrative.

However, poststructuralist curriculum researchers investigate inconsistencies, ironies, incoherencies, and intertextualities of the discourses used in any contention or positioning, including their own. They do so through their researching of how particular discourses create rules that govern what and how something can be conceived, claimed, and acted upon, as well as gaps and silences in such rules.

Poststructuralist researchers therefore assume curriculum conceptions, developments, and inquiries to be political acts in and through their

discursive constructions. As such, they are filled with incomplete, fractured, and deferred meanings that have the potential to subvert standardized and dominant curriculum constructions and principles. With fissured meanings, there always exist possibilities, then, to create fresh versions of particular content knowledges, practices, and inquiries.

Poststructuralist curriculum theorists also argue that educators' and students' subjectivities—the unconscious and conscious emotions and thoughts of individuals, their senses of themselves—are always in process, contradictory, produced historically, and reconstituted in discourse each time they think or speak. Indeed, poststructuralist theories posit that subjectivities, rather than being considered inherently part of a constant essence in humanist conceptions of the individual, are socially constructed in language, and thus can be considered sites of both struggle and potential change.

Researchers influenced by poststructuralist theories thus often examine subject positionings in relation to normative constructions of gender, race, ethnicity, age, sexual orientation, and ability, for example. Within these framings, the individual is a subject and is subjected to dominant discourses that often impose predetermined meanings. At the same time, in relation to content that might be studied as well as to others with whom the teacher or learner might interact, the individual also is a potential site for a wide range of subjectivities, and thus might generate fresh and unanticipated versions of knowledges and identities that cannot be predicted or controlled.

Poststructuralist theories that inform curriculum studies, then, do make possible, in differing ways, de-naturalizing critiques and forms of research. They do so by explicitly refusing humanist notions of universality and transcendence as well as of human subjects as always autonomous, unified wholes, separate or distinct from those discourses and cultural practices that regulate social activity and knowledge production. Poststructuralist theories enable curriculum researchers to reject versions of educational inquiry that assume an always-rational subject who can “discover” and then convey, through language that mirrors reality, versions of objective, decontextualized, and already-structured knowledge that then can be measured, predicted, controlled, generalized, and fully represented.

### Poststructuralist Theories That Inform Curriculum Research

Poststructuralist theories are impossible to totalize within one overarching definition, and such attempts to do so would be contrary to a poststructuralist's insistence on the instability of meaning, the arbitrariness of language, the power of discourses to control and limit. Rather, poststructuralist theories may be considered as bundles of differing discourses, methodologies, and practices that are by no means always related or compatible.

A wave of philosophers primarily emanating from France in the late 1960s, including Jacques Derrida and Michel Foucault, although differing in their theoretical and disciplinary foci, became known collectively as poststructuralists because of their major and sustained critiques of structuralism.

Structuralism, the intellectual movement and philosophical orientation most often associated with the Western discourses of Claude Levi-Strauss, Karl Marx, and Louis Althusser, and especially the work of the linguist Ferdinand de Saussure, attempted to explain how certain cultural content could be considered models of invariant structures. Drawing on Saussurean linguistics and the subsequent development of language as a field of study, structuralism extrapolated language to be a metaphor for understanding, for intelligibility itself, through which societal regularities reveal themselves and are taken as constituting reality. Those associated with structuralism claimed that cultural phenomenon could be examined according to the underlying formal systems out of which those phenomena emerged.

Structuralism, in great part, is situated in Saussurean linguistics. Saussure claims the arbitrary nature of the sign, wherein there is no “natural” relationship between the concept and the sound image. The only connection is convention—an underlying system of usage and tradition—that connects the sound image to the concept. Further, a sign is not a thing in itself. Instead, its identity springs from its difference from all other signs that surround it. Once a sign is isolated from its system, it “falls apart.” All systems of intelligibility, according to Saussure, operate as systems of difference without positive terms.

Structuralism did challenge the humanist and Enlightenment projects, which regarded history

as progress, placed humans at the center of creation, and privileged rational thought and Western culture. However, although poststructuralist theories incorporate structuralism's attack on humanism, a major poststructuralist break with structuralism involves theories that highlight how underlying systems that structuralism analyzed were themselves caught up in language and in discourses that were socially, historically, and culturally contingent.

Derrida criticized structuralism's presumption that language could be described as a static set of rules, instead demonstrating how those rules could be examined for their contingency and temporality. Taking Saussure's conception of language and differences, Derrida introduced the word *différance*, a word that does not exist in French spelled this way, a word that Derrida only provisionally called a "word" or concept. *Différance* combines the sense of the English verbs "to differ" and "to defer." Meaning is produced via the dual strategies of difference and deferral. Signifiers (sound or written images), which have identity only in their difference from one another, are subject to an endless process of deferral. Thus, any representation, in which meaning is apparently fixed, is only a temporary retrospective fixing.

Further, deconstruction, according to Derrida, is only what happens if it happens because it is not a philosophy, a doctrine, a knowledge, a method, a discipline, or a determinate concept. If it does happen, deconstruction enables one to critique structures that are held together by identity and presence, concepts that in Western philosophy represent transcendental order and permanence, manifested in beliefs such as the unified subject, the essence of an individual, and consciousness. Derrida used deconstruction, not to dismantle or reject or take things apart, but rather to reinscribe them in another way. In particular, deconstruction allows one to challenge any notion of foundational center that creates binaries—in which the first term of the binary most always indicates presence and power—and then to attempt to reconstitute that which has been previously inscribed. And that reconstitution must, in turn, be deconstructed.

Foucault's work, in particular, conceptualizes discourse—discursive practices that themselves form the objects of which they speak—as consisting of written or spoken words that are grouped

according to certain rules established within the particular discourse. Unlike structuralism's foundational sets of relations and systems, Foucault asserts that discourse is historically, socially, and culturally contingent, and that major analyses should focus on investigations of how it works, under what conditions, and how discursive formations and practices are part of nondiscursive practices. Discourses thus have both disciplinary and disciplining effects. Discourse, according to Foucault, defines fields of inquiry and knowledge as well as how rules within those fields govern what can be said, conceived, and acted upon.

Foucault's analyses of power/knowledge, the micropractices of power relations and their effects in the creation of subjects, includes his contention that power, rather than being hierarchical, proceeds in every direction at once. Power is not "owned," or deployed. Rather, it is exercised in that subjects are constituted within power relations, always within discourse. Indeed, there is no access to "reality" that is not necessarily mediated through semiotic systems, the most powerful of which is language.

### Poststructuralist Research Tracings in Curriculum Studies

The translation and dissemination of the work of Foucault and Derrida in the United States during the 1970s and 1980s enabled some curriculum scholars to take up major aspects of French poststructuralist theory by addressing the central roles of language, power, and discourse in any model or conception of curriculum theory, development, design or research. The further worldwide dissemination of French poststructuralist theory, including the work of French feminists Hélène Cixous, Luce Irigaray, and Julia Kristeva, encouraged curriculum researchers, within a variety of social and cultural contexts, to pursue poststructuralists' particular goal of troubling discursive and material structures, policies, and practices that limit or reify conceptions and enactments of curriculum or of educational "selves."

Some of the earliest poststructuralist work in curriculum, especially theorizing in the United States that grew from the initial movement to reconceptualize the curriculum field in the 1970s, drew on the theories of Michel Foucault, Jacques

Derrida, and Jacques Lacan to challenge essentialist notions of gender identity and to examine various gender discourses that often were linked to those same oppressive discursive systems these theorists sought to pull apart. Explorations of ways that discourse creates and is substantiated by the body and the unconscious followed; for example, some curriculum researchers drew from the psychoanalytic work of Lacan, especially his decentering of the humanist subject through his construing of the conscious and unconscious mind as products of language, of the symbolic.

Poststructuralists continue to exert major influence in qualitative curriculum research methodologies and practices. These researchers theorize the subjectivities of both researcher and researched as split, situated, and contradictory; advocate for textual practices of self-interrogation; simultaneously both use and immediately trouble typical categories of qualitative research, such as “validity” and “generalizability”; foreground the crisis of representation in their work; and move toward methodologies that foreground ambiguities, uncertainties, contradictions, and incoherences.

A number of feminist scholars, especially in Australia, the United Kingdom, and the United States, have drawn on the work of Foucault, in particular, as they work to understand and then to critique how modernist, humanist conceptions of “woman” have been constructed through and by dominant discourses in societies, in general, and in the field of education, in particular. Many, in their analyses of gender, rely on Judith Butler’s notion of an undesignatable field of differences within the category and the performance of “woman.”

Further, in investigating woman’s subjugated positioning within educational discourses that focus on binaries such as normal/abnormal or active/passive, many feminists use Foucault’s insistence on historical analyses as well as attention to the ways in which attempts to assert legitimate claims to knowledge often are caught up in the essentializing and patriarchal discourses that women want to combat. Exploring additional ironies to which poststructuralist theory points, feminist curriculum scholars also have investigated how radical discourses in education, including feminist pedagogy, paradoxically operate as regimes of truth, to use Foucault’s conceptualization. Some feminists especially have used aspects

of Foucauldian poststructuralist theory to challenge essentialist and unitary notions of voice and dialogue, two prominent components of critical as well as some versions of feminist pedagogy.

Poststructuralist curriculum researchers thus investigate discursive practices and relations of power that reify any educational processes or identities, or that underlie any one answer to the classic curriculum questions, what and whose knowledge is of the most worth.

## PRAXIS

---

The term *praxis* (from the Greek word *praxis* meaning “practice, action, doing”) relates to the

transformative possibilities afforded by reflective action. To understand how praxis has and continues to influence the field of curriculum studies, it is important to examine the dialogue related to praxis in curriculum, in the relationships between students and teachers, and in educational research and how, particularly in this field, praxis is tied to education as a form of democracy.

Historically, in curriculum studies, there exists tension between theory and practice, and praxis seeks to bridge that gap. The intersections between theory and practice officially began with Aristotle who explained that praxis is action taken by an individual who has been informed by knowledge and wisdom. During the Enlightenment, practice and theory became sharply divided, and they were considered as separate entities. For Karl Marx and Georg Wilhelm Friedrich Hegel and others influenced by Marxist thought, praxis became not just the action of an individual but the actions of a collective group. This shift to collective action opened up possibilities for the continuation of transformation on a global scale. Freedom, which is the ultimate goal for praxis, according to Hegel, can only be achieved through collective action; however, who is included in that group is closely tied to who controls the power. Antonio Gramsci charged those engaged in praxis to be attentive to the historical context in which they live. John Dewey believed that action influences theory and theory influences practice leading to the idea that praxis was a fluid motion between these two entities because all knowledge is experience.

The potential for empowering students is a notable contribution of praxis to curriculum studies. In *Pedagogy of the Oppressed*, Paulo Freire contends that words contain both reflection and action. If, for example, reflection is sacrificed for the action, both suffer. In the discussion that foregrounds his explanation of the banking system, Freire states that to speak a true word is the combination of action and reflection—and that is praxis. To find that true word is the work of change, the naming of the world is to transform it and be transformed by it. Authentic words make dialogue possible, and dialogue leads to humankind naming and renaming their worlds together through meaningful interactions. Therefore, for education, students should look to their own worlds and transform their own

situations. Those interactions result in a democratic curriculum.

Those engaged in curriculum studies extend Freire's notion of praxis from classroom interactions to inquiry and research in the field. Patti Lather, for example, challenges researchers to design praxis-oriented methodologies and methods that may produce social change and knowledge that would generate more opportunities for research that empowers both researcher and participant. Like Freire, she urges researchers to share their work with their participants to enable them to employ praxis in their own situations. Finally, praxis is also a component of critical pedagogy research, and scholars such as Elizabeth Ellsworth question whether this research really results in transformative action and whether this type of research sustains antidemocratic practices.

For Joseph Schwab, the practical is the duty of the teacher as well as the researcher, and he challenges educators from all disciplines to gather and address the important questions regarding curriculum, namely focusing on the success and failures of our schools. Some call for the increased involvement in students in creating school curricula. For example, Kenneth Sirotnik points out that including students in conversations about the curriculum enables them to play a part in transforming it. In her discussion of curriculum as product or praxis, Shirley Grundy questions the idea that curriculum itself can be praxis. Grundy and Ted Aoki agree, however, that praxis encourages a negotiation with the curriculum that results in unpredictable outcomes. The dialogue concerning praxis in curriculum studies has helped shaped the way scholars discuss some of the fundamental issues in education.

Interestingly (and perhaps ironically), Praxis is the name of the national teacher certification test used in the United States, which is written and administered by the Educational Testing Services.

## PRAYERFUL ACT, CURRICULUM THEORY AS A

---

Curriculum theory as a prayerful act is a postmodern approach to curriculum studies as theology where spirit is the life force within us. Prayerful in this sense is evoking the spirit to contribute to our empowerment, to our going beyond the strictly scientific process searching for evidence in the normal sensual domain. Curriculum theory in postmodern times gives a proper recognition of the spirit in curriculum studies.

In 1956, *Sputnik* brought caustic criticism of schools, prompting scholars to study and to develop appropriate practices and concepts to answer the critics. This led to a 50-year journey of teaching, researching, reflecting, serving, theorizing, and even praying/hoping for firm answers. At first, scholars found only glimpses and tentative ways to conceptualize curriculum theory as a prayerful act. Now in postmodern times, curriculum as a prayerful act is an appropriate conceptualization for a complex process.

In retrospect, scholars were looking for a curriculum theory appropriate for the postmodern age, an inclusive theory, one based on “both/and” rather than “either/or” orientations and where curriculum is theology, not where curriculum is technology. The need to be inclusive, to consider spirit and aesthetics as well as intellect and emotions, and to include science, literature, folklore, and religions in the curriculum led to the concept of “curriculum as theology.” Mythology and archetypal psychology contributed to understandings and needed to be part of curriculum studies and theories. Educational myths that are considered the truth, but are not, are dysfunctional myths and call for study and replacement. Mythopoets’ research goal or approach is known as *demythologizing*. Including the search for “spirit” and

“spiritual” in curriculum studies has led to the concept of “curriculum as a prayerful act.”

Curriculum researchers/mythopoets are guided by, at least, the following principles. Getting into and out of the spirit; this process is often called *transcendence*. An example is “losing” oneself when experiencing an inspiring piece of art or literature, or the “aha” of making a scientific discovery. The myth of spirit as ineffable yet representable is replacing the “scientific” notion that because the spirit cannot be measured, it is not appropriate for the curriculum. Spirit, albeit not measurable, is represented and experienced in good literature, art, theology, and scientific studies. Mythopoets most often study and represent the spirit/spiritual in presentations and publications, poems, stories about transcending, nurturing, practicing, criticizing, self-studies, therapy, and experiencing awe-inspiring works of art, sermons, music, and letter writing. An all-inclusive term for their work is *narrative*. In qualitative research, *narrative* means telling or writing stories and analyzing them for meaning.

Although the goal of the mythopoets’ research is known as demythologizing, the methods, ways of doing their research, are *hermeneutics*, *heuristic inquiry*, *autoethnography*, and *autobiography*. Using a number of research methods in a study is called *bricolage*, and the researcher, besides being a mythopoet, is a *bricoleur*. (A bricolage is a name and metaphor for a patchwork quilt; the bricoleur is the quilter. The patchwork quilt where the patches are held together in meaningful ways is the metaphor for demythologizing using a patchwork of appropriate research methods for the tasks at hand.)

Curriculum theory as a prayerful act, then, is a curriculum theory inspired by the spirit/spiritual in the curriculum and in curriculum studies and research, by being appropriate for the postmodern era, by being inspirational not religious in the sense of violating the separation of church and state in the United States, and by being able to join with the students who are motivated by school spirit. Many students are mythopoets who engage in demythologizing dysfunctional myths and represent their discoveries in poetry, art, science, volunteering, and in athletics. One such dysfunctional myth is that youth cannot grasp complex studies such as economics or anthropology. Scholars develop economics and anthropological curricula

for first graders and good teachers teach them. If curriculum theory as theology can lead to transcendence, to beauty, to understanding, or to behavioral change, why can it not be considered a prayerful act?

## PREPARING INSTRUCTIONAL OBJECTIVES

---

*Preparing Instructional Objectives* by Robert F. Mager was first published in 1962 as *Preparing Objectives for Programmed Instruction* by Pitman Learning. The publication describes the importance of being explicit when writing instructional objectives, the qualities of useful objectives, and the components of effective instructional objectives. Instructional objectives can be valuable tools for perceiving and guiding curriculum studies. They reveal instructional expectations to students; help the teacher select instructional methods, materials, and procedures; and help the teacher determine appropriate assessments.

Mager, an influential researcher and learning theorist who viewed learning experiences through a behaviorist or objectivist approach, developed the concept and value of behavioral instructional objectives. As a behaviorist, he saw learning as occurring only when student behavior was changed in concrete, observable ways. In *Preparing Instructional Objectives*, Mager describes his view of effective instruction through the measurement of specific outcomes. This book assisted many instructors in formulating and writing objectives. In this book, Mager explains that instructors can

best help students learn when they know what the students' current instructional needs are and what the result or goal is for a particular lesson or learning experience. For example, if the goal is for a student to learn to write his or her name, knowing what the student already knows and the intended result will help the instructor determine what materials are needed, what method will be most effective, what steps to take to help the student reach the end goal, and how the instructor will know the student has reached the designed goal.

In *Preparing Instructional Objectives*, Mager defines instructional objectives as specific outcome-based statements of measurable student behaviors that result from instruction. They are specific and outcome based in that they explicitly state what the student is expected to do as a result of instruction. They provide means to measure student behaviors that can be heard or seen as evidence the student has successfully achieved the objective. Instructional objectives do not describe the process or instruction but rather the results of instruction.

This book made a significant contribution to curriculum studies. In the 1960s and 1970s, many public school teachers were required to create behavioral objectives as a critical part of their daily lessons. Workshops taught teachers Mager's model for writing behavioral objectives, which were seen as a way to increase learning and retention through specific and measurable curriculum design.

Critics of this book debated the value of objectives as related to planning and delivering curriculum and instruction. These critics objected to using behavioral objectives to shape instruction because they saw learning not as changes in behaviors that reflect conformity with measurable outcomes but as a process. Critics said that behavioral objectives disregarded diverse ways of knowing, behaving, and learning. They view learning as less structured and predictable than the perspective of learning represented in behavioral objectives. They see learning as more self-directed and child-centered than objective-directed and teacher-centered.

*Preparing Instructional Objectives* has had lasting importance in the field of curriculum studies. Educators are still writing and using behavioral objectives as part of their curriculum design when behavioral changes are the curriculum outcome. However, given more progressive views of learning, learning objectives are being stated less

in behavioral and prescriptive terms and more in terms of learning as a process.

## PRIVATIZATION

---

Privatization, generally, is the withdrawal or shifting of the government's assets, functions, activities, and possibly entire institutions to the private sector. In education, privatization occurs when local, state, and national policies are enacted that support free market entry into the public domain of schooling. Four types of educational policies can result in privatization: (1) the cessation or disengagement of the government from responsibilities in providing educational goods and services, (2) the explicit transfers of public school assets to private ownership, (3) the financing of private educational services through contracting-out or vouchers, and (4) the deregulation of entry into activities, previously restricted to public providers, to private entities. Although the various forms of private reforms fall under the heading of privatization, there is no single privatization plan throughout the United States as a result of the history of local and state control in public schooling.

Milton Friedman, a free market economist of the Chicago School, first proposed privatization for public schools in 1962 via government-funded vouchers for parents to choose and purchase the services of private schools for their children. By 1998, provoucher corporations and foundations had committed substantial funds to establish

voucher programs in 41 cities. In 2003, Congress passed the District of Columbia School Choice Incentive Act, which provides vouchers for low-income families to send their children to private schools of choice, including religious schools. Research on the effectiveness of private school choice has focused on students' scores on standardized tests and has been hotly contested.

Privatization of public school services increased through the 1990s and is included in the policy provisions of the No Child Left Behind Act of 2001 (NCLB), such as policies and funding for charter schools and for the contracting of outside providers for the supplemental educational services.

Charter schools, as defined by the NCLB, are essentially public schools that are exempt from significant state or local regulations. They are designed to foster innovative teaching, curriculum and school organization, are funded publicly, cannot be affiliated with a religious institution, and cannot discriminate on the basis of age, race, gender, religion, ethnic origin, or disability. They vary from state to state, can contract with private corporations to provide services within the school for instruction and management, and can do private fund-raising. They also are granted waivers from their respective states in regard to state educational requirements; for example, in Pennsylvania, charter school legislation does not allow for teacher tenure and requires that only 75% of the employed teachers be certified teachers. As with the research on private school choice, results regarding student academic achievement for charter schools are mixed and vary greatly because of the wide variety of different forms of charter schools.

The contracting with a private corporation or a not-for-profit entity to provide supplemental services, such as managing public schools; custodial, transportation, or food services; and curriculum and assessment resources is also increasing. For example, the Success for All Foundation, a not-for-profit entity, provides scripted curricula and an assessment, 4Sight, that is aligned with a state's assessment system as required by NCLB. For-profit corporations such as Huntington Learning Center and Sylvan Learning Center provide after-school tutoring paid by federal NCLB monies. Public school districts and charter schools can also contract with for-profit and nonprofit educational management organizations to operate and manage

the whole school. Edison Schools is the most well-known and largest of these companies; others include National Heritage Academies, Mosaica, and White Hat Management.

An additional form of privatization includes the sale to private corporations of access to public school children as a form of increasing school revenue or providing student services. Examples include Channel One, a broadcast service of news features with commercials in approximately 25% of U.S. middle and high schools; Pizza Hut's BOOK IT! reading incentive program; and computer purchasing incentives.

Privatization of education has fueled extensive debate in the United States and internationally. Policy debates for and against privatization have centered on four criteria: (1) freedom of choice for parents to determine their children's form of schooling; (2) the efficiency of private forces to produce better results given the resources; (3) the question of equity in educational resources, opportunities, and results according to gender, social class, race, language origins, and geography; and (4) the social cohesion that results from a common educational experience. Advocates for privatization generally tout the importance of parents' choosing the kind of school or service that best represents their values, educational philosophies, religious teachings, and political views for their children and argue that student achievement will be higher per capita expenditure in private schools. As for equity, advocates contend privatization provides superior opportunities for students locked in failing schools. Opponents, on the other hand, argue that privatization reforms are limited to small numbers of students and that private school vouchers and charter schools rob resources from existing public schools and exacerbate the current inequity in educational resources according to social class, and so forth. Opponents also contend that a marketplace of private schools and private entities within public schools undermines a major public purpose of schooling; that is, the provision of a common educational experience accessible to all children that reinforces national political, economic, and social structures. They also contend that privatization eliminates the transparency that is a function of public accountability.

## PROBLEM-BASED CURRICULUM

---

Problem-based curriculum is designed to experientially engage students in processes of inquiry into complex problems of significance and relevance to their lives and learning. It is intended to challenge students to pursue authentic questions, wonders, and uncertainties in a focused way, which enables them to construct, deepen, and extend their knowledge and understanding. Problem-based curriculum steps away from typical notions of curriculum in that it positions students as stakeholders, and as knowers, in both teaching and learning processes. It organizes curriculum in holistic ways, around problems that are messy and multiple, foregrounding the development of processes of learning, attitudes, and dispositions as well as the acquisition of content knowledge.

The four curricular commonplaces conceptualized by Joseph Schwab—teacher, subject matter, student, and milieu—help make visible the structure and interaction within a problem-based curriculum. The teacher examines subject matter to determine what big ideas are central to one or more disciplines, have the potential to fascinate students, will connect to students and their lives in a variety of ways, and have enough richness and tension to hold students' curiosity for an extended period of investigation. Examples of big ideas might include such concepts as pressure and force, identity, and freedom and conflict. Using situations

arising in local contexts and the lived experiences of students, the teacher, parents, family, and community members, the teacher then shapes a particular problem-based curricular unit. Defined learning outcomes and curricular standards are pursued within this unit through student-initiated and choice-driven inquiries.

Problem-based curriculum begins with an initial experience in which students are challenged with a problematic situation, one that prompts their thinking and causes them to ask a multitude of questions. It then leads to a series of central experiences in which students decide what is personally meaningful to them, plan their inquiries, engage in their explorations, compile their information, think hard about their findings, and determine what they have learned in relation to the problem they first posed. Throughout this central time, the teacher is an active facilitator of student inquiries, leading discussions; teaching problem-solving, thinking strategies, or process skills; providing responses; asking probing questions; directing students to resources; and teaching or supporting group and collaborative skills. Rather than being preplanned, the teaching is responsive and contextual, sometimes done individually, at other times in small groups or with the whole class. Problem-based curriculum concludes with a culminating experience in which students share their inquiries with one another and, typically, with a broader audience of vested interest.

Thoughtful presentation of the problem is critical to problem-based curriculum. Problems must be complex enough that there is a need to seek many perspectives on the issues, to engage in collaborative inquiry, and to generate multiple possible solutions. The problems have an authenticity that holds meaning for the students, enables them to assume ownership of the problems, and results in findings of significance in the broader context of their lives. Problems must invite a deep approach to learning—to inquiry, thinking, and reflection—which leads to shifts or changes in students' knowledge. At the same time, they leave room for students to discover that knowledge is tentative, always reflective of a moment in time, and open to continued shifts and changes. Rich problems invoke in students both the motivation and the ability to think in integrated and integrative ways with a high degree of sophistication.

Problem-based curriculum reflects an epistemological stance rooted in experience. John Dewey, a proponent of progressive education, argued for education that prepared individuals for life, not solely for work. He believed in situating learning in the context of community and in problems of significance that demanded thinking, sense making, and problem solving. As with Dewey, the emphasis on reasoned activity within problem-based curriculum positions curriculum content as important *in relation with* the activeness of the inquiry. Problem-based curriculum invites students to apply the knowledge they gain and, in so doing, extend and enhance it, moving beyond their initial conceptions to the generation of new possibilities and innovations.

## *PROCESS OF EDUCATION, THE*

---

Authored by cognitive psychologist Jerome Bruner, *The Process of Education* is a report of the Woods Hole Conference of 1959, a watershed event in the history of curriculum studies. This educational classic's stated intent was to discuss new efforts in curriculum design that had been spurred by federal funding in reaction to Russia's success with *Sputnik*. However, despite the meeting's focus, only three educators attended, the principal participants being scientists, mathematicians, and psychologists. Emphasizing the structures of academic disciplines

as the organizing principle for the curriculum, Bruner's interpretation of the conference proceedings quickly became the foundational statement for a new national curriculum reform movement. In effect, the movement represented the transference of responsibility for curriculum development from curriculum professors and K–12 educators to scholars in the academic disciplines. As a result, the curriculum field went into crisis, leading to a transformation that has variously been termed its reconceptualization or renaissance.

Other consequences of the new reform movement were equally dramatic. As Bruner interpreted the importance of the movement, educational psychologists reasserted a place in curriculum planning that they had deserted earlier in the century for the study of aptitude and achievement. With their focus on the learning process, however, psychologists' foray into curriculum tended to cast educational problems in terms of learning theory. Long-standing curriculum scholarship on the implications of balance among learner needs, societal needs, and subject matter was neglected. In addition, the movement's impetus—the *Sputnik* crisis—provided a rationale for the federal government to assume broad new responsibilities in education. Congress allocated massive funds for curriculum revisions, especially in math, sciences, and foreign languages. However, control of this money did not fall to curriculum professors, who had been scapegoated along with professional educators as the cause of U.S. technological shortcomings. Rather, much of the money went to discipline-based scholars, who assumed that curriculum could be generated centrally and disseminated to teachers who would be trained to use them. Such curricular efforts were already underway in physics, biology, and chemistry when Woods Hole participants met to compare their efforts and discuss further possibilities.

The conference was organized and financed by the National Academy of Sciences, the U.S. Office of Education, the Air Force, the National Science Foundation, and the Rand Corporation, with additional support from the American Association for the Advancement of Science and the Carnegie Corporation. Bruner's summary of the proceedings laid out the hypothesis that any subject could be taught effectively in some intellectually honest form to any child at any age. The goal of curriculum and

instruction was to be intellectual development. The central themes for proceeding in curriculum work were “structure of learning,” “readiness for learning,” and the “spiral curriculum.” The appropriate pedagogy would mimic the investigative strategies of discipline specialists.

Bruner recounted the sense of a profound scientific revolution that the country was experiencing at the time. In 30 years, everyday life had been transformed by the wonders of radio, television, and the automobile. Hopes ran high that education would be substantially transformed now that scientists were involved. This new optimism was premature, however. Scholars within the same discipline did not always agree on its basic structure or that the concept of structure as an organizing principle was valid. Many teachers rejected the new curricula because they were too difficult for the great number of students of average ability or because they challenged traditional pedagogical practices. In addition, in the mid-1960s, politicians began to call for evaluation studies to prove that federally funded programs were accomplishing their goals. The results undermined confidence in programs based on top-down models that ignored teacher input. Writing in 1971, Bruner recalled that discipline-centered reform had made sense framed by the cognitive revolution in psychology and the military and technological emphasis of the cold war. It became clear, however, that the approach erroneously assumed that students lived in a sort of educational vacuum, shielded from larger community and social concerns. In later years, he went on to investigate the role of culture in learning.

## PROFESSORS OF CURRICULUM

---

The organization known as the Professors of Curriculum (POC) had its beginnings in 1944 when Hollis Caswell of Teachers College, Columbia University, invited a group of colleagues to meet informally to discuss their work. They began their meetings close to the time that the Association for Supervision and Curriculum Development (ASCD) was formed and began meeting formally at the annual ASCD Conferences in 1945. These individuals were seriously committed to informality (with no president or secretary). They did, however, decide to select a “factotum” each year to call the group together, and to be in charge of handling any issues or problems the group might have in coming together each year, such as hotel meeting space and refreshments. Attendance was extremely important, and failure to come to at least one meeting every three years would result in that member being dropped from POC. Initially, membership in POC was around 35, but grew to 75 by the 1970s and was more than 100 by the late 1990s. This somewhat informal group has as its basic criteria for membership that each individual actually teach a curriculum course at a college or university. In more recent years, a number of international members have been asked to join POC based on their teaching and scholarly work. As members leave the organization, a membership committee yearly recommends potential new members and invites them to the yearly meeting. At the close of each annual meeting, current members hold a business meeting to elect a new factotum for the next year, vote on potential new members, and discuss any financial issues.

The group continued meeting in conjunction with ASCD until the late 1970s when the annual American Educational Research Association (AERA) conference began attracting college professors of curriculum and supervision. The POC decided to hold a second formal meeting at AERA in 1977, with the ASCD meeting still identified as the main meeting and where the formal business meeting took place. By the late 1990s, a third organization—the American Association for Teaching and Curriculum (AATC)—began attracting curriculum and supervision professors, so a third meeting place was identified in 2000. By

2000, the POC members could meet at any of three conferences—ASCD, AERA, or AATC—to keep their membership active in POC. Informal business meetings were being held at both the AERA and AATC conferences, with the formal business meeting remaining at ASCD until 2006. In 2006, the membership of POC voted to sanction only one meeting per year, and that meeting would be held in conjunction with the annual AERA Conference.

Membership for 2008 was limited to 125 regular members with emeritus status upon request. At the 2008 meeting, there were 111 regular members with an additional 54 identified as holding emeritus status. Membership continues to be by invitation only with a panel of POC members reviewing teaching responsibilities and supporting scholarly documentation.

## PROGRESSIVE EDUCATION, CONCEPTIONS OF

---

The term *progressive education* proves to be as amorphous as the term *curriculum* itself. Little consensus exists, and the concept, although often not specifically defined, leads to much misunderstanding. When used in the field of curriculum studies, progressive education adopts more of an ideological definition, representing a dynamic, transactional view of learning, and a focus on the interests of students. Such a working definition, however, provides little clarity when the term is so widely and casually used to describe a wide array of educational practices.

In *The Transformation of the School*, Lawrence Cremin warned against formulating any capsule definition of progressive education, maintaining that no common description exists nor could exist partly because of the character of the movement that necessitated conceptual diversity and differences. At the 1938 annual Progressive Education

Association (PEA) meeting, a committee reported on its efforts to define the term and, although a statement was produced, nearly the entire group objected, explaining that *progressive education* is not a definition but “a spirit.” At times too focused and at other times too comprehensive, the term was viewed by Herbert Kliebard as vacuous and mischievous and carefully avoided in the writing of *The Struggle for the American Curriculum*. Even in the final report of the PEA’s Eight Year Study (viewed as a defining progressive education document), Wilford Aikin never used the term *progressive education* except once in reference to a quotation.

Nonetheless, a vague and widely shared definition of *progressive education* emerged during the 1950s (continuing to today), oriented toward elementary education practices and defined by a “child-centered education” moniker focusing on the interests of children. With “learning by doing,” “teaching the whole child,” and “fostering creative expression” slogans characterizing progressive education, the practice was brutally criticized by educational critics who felt the “movement” had eliminated academic standards and fostered a generation of self-indulgent children.

One crucial issue pertaining to how progressive education is conceived stems from whether the term represents a distinctive set of beliefs or whether the definition arises from historical fiat; that is, whether progressive educators are defined by a set of beliefs, or whether progressives are defined as those educators who lived through the Progressive Era. Cremin, for example, situates the genesis of progressive education in the years immediately following the Civil War. Like him, most educational historians view progressive education as an outgrowth of the U.S. Progressive Era. From this perspective, the movement comes to fruition in the late 19th and early 20th centuries, beginning with Frances Parker’s school in Quincy, Massachusetts (and then Chicago’s Parker School), continuing through John Dewey’s laboratory school at the University of Chicago, and followed by developments at the Gary, Indiana, schools, Winnetka, Illinois, schools, and Lincoln School and Dalton School in New York City and with the (diverse) writings of Ellwood Cubberley, William Wirt, Marietta Johnson, Caroline Pratt, and Margaret Naumburg. Progressive education seems,

then, to have been codified into an ideology before the formation of the PEA. These practices differ strikingly from progressive education work of the 1930s and the secondary schools of the Eight Year Study, as portrayed at the Denver public school district, Des Moines public school district, Ohio State University (public) School, Tulsa public school district, and reflected in the diverse practices of Caroline Zachry, Alice Keliher, V. T. Thayer, Harold Alberty, Eugene Smith, Harold Rugg, and Boyd Bode.

One of the many difficulties in describing the term is that progressive education was often viewed as “a spirit” of reform, placing itself in opposition to traditional practices, rather than as a unified educational practice. Eugene Smith, one of the founding figures of the PEA, described true progressive education as constantly changing and adapting to present-day conditions and needs and drawing on new research and discoveries in the field of education. Another complicating factor for a clear description is that anyone could proclaim himself or herself as a progressive educator, thus aligning with the beloved Dewey. Both Ralph Tyler, the developer of the seemingly unprogressive education Tyler Rationale, and Ben Wood, the founder of the Cooperative Testing Service that has led to the current nonprogressive, high-stakes testing movement, maintained that they were progressives whose work was guided by the writings of Dewey. Yet, neither Tyler nor Wood would be considered exemplars of progressive education practices in the field of curriculum studies.

Throughout the years, various educational and curriculum historians have provided more specific designations for the different orientations and ideological collectives that formed under banner of progressive education. Cremin classified progressive educators as “scientists, sentimentalists, and radicals.” Kliebard used the descriptor “social meliorists,” David Tyack developed the configuration of “administrative progressives” and “pedagogical progressives,” and Rugg distinguished between “scientific methodists” and “project methodists.” Craig Kridel and Robert Bullough, attempting to bring attention to progressive education’s experimental efforts at select secondary schools, have identified a group of “Eight Year Study progressives.”

Students of the field of curriculum studies should look for whatever idiosyncratic definition is being used by authors and, most importantly, should not assume that all progressive education is based on simplistic conceptions of either child-centered curriculum, the project method, or social efficiency.

## PROJECT-BASED CURRICULUM

---

Project-based curriculum represents an ideological framework and a practical approach to how classroom inquiry may be enacted. Within project-based curricula, students engage in studying authentic problems or issues centered on a particular project, theme, or idea. Often the term *project-based curricula* is used interchangeably with *problem-based curricula*, especially when classroom projects focuses on solving authentic problems. The nexus for the project may be suggested by a teacher, but the planning and execution of contingent activities are predominantly conducted by students working individually and cooperatively over many days, weeks, or even months. This type of curricular method is inquiry-based, outcome-oriented, and associated with conducting curriculum in real-world contexts that are related to naturalistic endeavors rather than focusing on curriculum that is relegated to book or rote learning and memorization. Assessment of

project-based curricula is commonly performance-based, flexible, varied, and continuous.

Project-based curriculum challenges the often-prescribed scope, sequence, direct-instruction, and disciplinarity commonly linked to traditional schooling. As a result of its reliance on actual context in natural settings, project-based curriculum is often hands-on, emergent, evolutionary, and focused on integrated endeavors that are interdisciplinary or cross-disciplinary. The organic and experiential aspects of project-based curricula promote knowledge, skills, behaviors, and dispositions through rigorous learning structured in such ways that it may be transferred to other situations and contexts in school, or in one's own life. As a result, project-based curriculum is relevant to the immediate participants in classroom endeavors as it resists banking conceptualizations of education. Project-based learning nurtures student-centered environments that are outcome-oriented, yet situated in learners' lives, and learners are focused more on understanding than on regurgitation. In this sort of curriculum, students confront an issue where there is more than one possible solution. Once a project or an issue is identified, students are provided the space and opportunity and challenged with the responsibility to analyze, discuss, and work together to solve a problem or work through a multidimensional project that ties multiple or all the disciplines of knowledge into one cohesive unit of study. Because of the comprehensive nature of project-based curricula, the issues associated with a particular project provide rigorous content that can be aligned to state standards, but is taught while focusing on what interests and motivates students in a low-stakes setting.

Within the field of curriculum studies, the trajectory of ideas related to project-based curriculum began with the concern of how teaching and learning should be conducted in schools. Both the framework and teaching method stemmed largely from the broad question of what was or should be the role of school in society during the Progressive Era. Project-based curriculum, therefore, is rooted in the U.S. progressive education movement of the 1920s and 1930s because during this time the great debate of how school curricula should be enacted was at full force. Questions surrounding progressive educational ideals, whether school should be reflective of these ideals, and societal

demands during this time pushed multiple dimensions of how project-based curriculum could serve communities and the needs of the U.S. public through schooling.

Early theorists in the field of curriculum studies provide much guidance for current conceptualizations of project-based curriculum, although these practices have certainly flourished beyond the curriculum studies field in many realms of education. John Dewey notably discussed the importance of experiences in learning and the progressive nature of subject matter that focused learning beyond a traditional, simplistic, and subject-area relegation. William H. Kilpatrick contributed to this teaching phenomenon through his proposal of “The Project Method” in the early part of the 20th century. Kilpatrick sought to discover a concept that would interconnect various elements and processes of education and life while focusing on students’ actions through what he deemed purposeful acts that furthered moral responsibility. Other curriculum studies scholars’ work in the areas of how best to enact curriculum had a great affect on current incarnations of project-based curriculum. Some of these scholars include L. Thomas Hopkins, Joseph Schwab, Paulo Freire, and James Beane.

From the 1930s to the 1980s, Hopkins’s work on integrative curriculum; his distinction between a living or alive curricula compared with one that focused on issues, topics, and people of the past; and placing the behavers (students) at the center of learning experiences had a profound affect on how project-based curriculum could and should be enacted within the curriculum studies construct. Schwab’s ideas during the 1960s and 1970s related to practical inquiry and the interaction between what he called the commonplaces of education (teachers, students, subject matter, milieu) supports foundational ideas related to project-based curriculum because it places actual classroom participants as key components to how the learning environment is or should be constructed. Similarly, Freire’s ideas of a problem-posing curricula that focused on having those that have been oppressed reading their world rather than prescriptively being told what is important to learn and how to learn lends itself to the sort of problem solving associated with project-oriented approaches to classroom practice. In more recent decades, building on the theoretical guidance of Dewey,

Kilpatrick, Schwab, Hopkins, and Freire, Beane suggests that project learning in classrooms can be achieved through an integrated curriculum—learning that highlights the interdisciplinarity and interconnectedness of subject matter—related to the social concerns of students and the environments in which they learn. Beane argues that this sort of curricula allows the interests of the students to be at the forefront of learning, while arbitrary compartmentalization that decontextualizes curriculum and learning will be lessened. Overall, many current educational practices have been strongly influenced by the curriculum studies literature and its theoretical basis for project-based learning.

## PROJECT METHOD

---

The project method first appeared in 16th-century Western Europe, but its origins in the United States are found in the fields of industrial and agricultural education during the late 19th century. In its most fundamental form, the project method represents a curricular-instructional practice where classroom experiences focus on activities planned and implemented by students. Attributed partly to reconciling the importance of students’ interests and engagement in learning, the project method was also oriented toward displaying real-life experiences as a component of the school curriculum.

In 1918, a little-known university professor at Teachers College, William H. Kilpatrick, published a detailed description of the project method in the *Teachers College Record*, and the article became a national sensation. Though Kilpatrick later saw the need to redefine aspects of the project method, partly because of the criticism of Boyd H. Bode and William C. Bagley, the 1918 essay defined a project as having two necessary components: (1) a hearty, purposeful act and (2) an activity conducted in a social context. Critics questioned this conception of the project method if the participant's interests in an activity waned and the act was no longer purposeful. Further, what constituted a social context proved unclear as described by Kilpatrick.

Kilpatrick categorized four types of projects, those oriented around concepts, experiences, problems, or knowledge/skills (also at times described as problem, learning, construction, and enjoyment projects). Later, in describing his "method," Kilpatrick added distinctive instructional phases of purposing, planning, executing, and judging. At a time when many elementary and secondary school teachers were interested in incorporating aspects of progressive education and focusing the curriculum on the concept of experience, Kilpatrick's guidelines provided observable and tangible progressive practices. Further, with attention on child-centered curriculum, the concept offered clear justification for changing practices in the classroom. The project method received its greatest practical support from case study research conducted in Missouri by Ellsworth Collings, a doctoral student of Kilpatrick, whose dissertation research was published as *An Experiment With a Project Curriculum*. Popularized by Kilpatrick, Collings documents the success of this curricular method as he later expanded his conception to include exploratory, construction, communication, play, and skill types of projects. The contemporary German scholar, Michael Knoll, painstakingly reconstructed Collings's case study and concluded that the research never took place as it was originally described in the 1923 publication. Nonetheless, the project method was implemented and adapted in many forms throughout the United States during the 1920s to 1940s and remained one of the most popular and distinctive practices of an experience-based curriculum and progressive education school.

Within the history of curriculum studies, other distinctive conceptions of the project method were described by John Dewey, Harold Alberty, David Snedden, and W. W. Charters; however, the most extensive and contrasting view was published in 1922 as a full-length book entitled *The Project Method of Teaching* by John Stevenson. Although the curriculum for Kilpatrick's project method could take any form as long as the activity was embraced with "purposefulness," Stevenson (and others) confined the topics of a project to those of "a problematic act carried to completion." And although Kilpatrick's method called for an element of social context for which its definition seemed all encompassing, Stevenson defined the educational context as "the natural setting" for the problematic act. Though Stevenson's definition and description of the many other conceptions of the project method prove equally problematic, what appears quite evident is that many authors and many forms of the project method were underway in classrooms throughout the United States. Even though Kilpatrick distanced himself from the project method at the end of his career, the method, similar to the use of the term *progressive education*, was applied and misapplied to the point where no distinctive set of concepts or practices provided a unique and commonly accepted definition of the term. The project method and Kilpatrick's writings were rediscovered in the 1960s in Western Europe, notably Germany, and during the 1970s and 1980s, the British primary school movement popularized this instructional method in Britain and the United States.

## PSYCHOANALYTIC THEORY

---

Like the signifier “education,” psychoanalytic theory may be associated with a wide range of events, histories, ideas, people, practices, arguments, hopes, failures, fears, fantasies, institutions, and cultural (nonclinical) applications. Although both are an experience and a means to modify it, psychoanalytic theory signifies deconstruction of the subject’s intentions. This theory takes apart and then reconstitutes explicit or intended meaning to reach what is latent and implosive in any utterance: something unsaid and unintended, something unconscious that exerts and pressures, in negated form, the fantasies, anxieties, and desires of the speaking subject. How words come to matter, lose their object, signify lack, and then resist this thinking are all met by its method and goal of free association, that is, speaking whatever is in one’s mind with an interest in narrating what stops it short: censorship, judgment, or moral anxiety. Free association is the capacity to make a clearing from that which is its poor relation: neurotic symptoms, nagging thoughts, obsessions, inhibitions, compulsions, and ruinous, repetitive acts. From this estranging material, the accidental speaking subject becomes curious about her or his inner world and its play of affect. Simply stated, psychoanalytic theory is a language, a structure, a method, and a practice for listening and interpretation. It approaches language as both a momentous event and the means for symbolizing the reverberations of its excesses and revenants. Psychoanalytic theory opens the study of curriculum to what is most subjective and unconscious in knowledge and our attachment to it. This entry discusses the role of psychoanalytic theory in learning, the schools of psychoanalytic thought and their application to curriculum studies, and the role of psychoanalytic theory in literacy.

### Learning and Psychoanalytic Thought

Learning is presented as the means to change not only what is in one’s mind but the mind’s structure. The mind’s content, however is seen through a psychological prism, expressing, though displacement and condensation, the drives and idiomatic desire. Ideas are erotically linked to images, people,

fantasy, fragments of lost events and relations, and to pieces of the body, all named “objects” or “imagos.” The ongoing problem of learning entails learning to live with others on the way to becoming an “I.” Education is presented as both needed and as subject to its own pathologies. Any learning is learning from uncertainty and conflict and therefore becomes the capacity to tolerate the mental pain of thinking from the unknowable and the incomplete. Yet this means that learning is inextricably tied to anxiety, a signal of danger that links the external and internal worlds. The interest is in moving from frustration to symbolization. Although this view of the human leans on what is tragic in the human condition, it is also concerned with what is beyond the tragic, namely processes that may bring one to a larger truth: creativity, imagination, aesthetics, and the desire for symbolization.

The primary concern is with the trauma of human suffering and its congealed expressions that animate problems within the demand for happiness and then reverberate in experiences of unhappiness, melancholia, and mourning. It proposes that the human suffers from meaning through a series of developmental losses, all affecting the fantasized body: loss of the breast, the genitals, the other, one’s own body. These losses the finite erotic human must suffer and then signify what these losses come to mean in relations of love, hate, knowledge, and how they seamlessly blend into work, sociality, and political life. Although the body and its oral, anal, phallic, and genital phases are the raw material of symbolization, these metaphorical phases coexist throughout life and are found in situations of aggression and fantasy expressed in behaviors such as stealing, hoarding, copying, name-calling, and more devastating orders of social destruction. Psychoanalytic theory emerges then from problems of eros in human understanding and misunderstanding and opens questions into the ways the external world is internalized and, too, how the internal world is externalized through both language and bodily symptoms. It asks the question, from where does misery come? Its theory addresses such issues as the human’s enigmatic resources of existential life such as dreams, art, and music, to speculations on human development and its psychic life, to paradoxes of self/other relations, to that which resists or escapes the anchor of meaning, and then, onto questions of

the theory itself: how its theory affects therapeutic action, or the transformations of both the theory and its subject. Its boundaries are as porous as the imagination.

Psychoanalytic theory is an affected theory, in the sense that the key problems of concern focus on the human's capacity for unity and destruction and for incoherence and paradox. Further, psychoanalytic theory includes the idea that the theorist is subject to and embodies every one of its concepts, including resistance to psychoanalytic theory. Just as educational theory must draw from the childhood of the theorist's education in the sense that the theorist is never a stranger to education, so, too, does a psychoanalytic theory lean upon the thinker's intrapsychic and interpsychic projective identifications, ego defenses, wishes, and unconscious life. What separate psychoanalytic theory from educational theory, however, are the former's involvement in the subject's madness, breakdowns, incoherence, and unconscious life, with the view that because the human's condition is a nervous condition, it is subject to fantasy, to projections, and to the confusion of pleasure and pain or good and bad.

### Schools of Psychoanalytic Thought

Psychoanalytic theory began with the research of Sigmund Freud; during the 20th century, psychoanalytic theory evolved into a post-Freudian cacophony of contemporary schools: Classical Freudianism or ego psychology, British object relations, and French psychoanalytic traditions. These dominant orientations, revised by clinical practice, new schools of psychoanalytic thought, contemporary cultural theory, and the pressures of the talking cure, posit universal dilemmas in becoming human. They include a view of the formative impressions of infancy, which give both the capacity for anxiety and the need to become a speaking subject. The developmental progression is from primal dependency and helplessness to need, to demand, to pleasure, and to sublimation. Each phase constructs historical reality and fantasy. This temporality is recursive and defies linear and binary reason, although narrating chronology by situating its causes and catalysts are the means for the human to order what is essentially a chaotic universe. Social, historical, cultural, and political

experiences carry traces of human natality and its neoteny and infantile sexuality that founds group psychology in the form of parental, cultural, and institutional life. Psychoanalytic theory can be understood as a means for approaching existential questions of life and death, and aggression and Eros in the work of learning to live. These affective dynamics are the basis of the transference: the exchange of love and authority with desire and knowledge. The transference is the basic mechanism of learning and not learning.

Although each of these three schools of psychoanalytic thought may be considered as variations on the theme of the relations and nonrelations between psychological reality and historical reality, all schools are interpretive variants on Freud's insight that humans suffer from meaning and convey what is missing through the symptom. There is concern for the uses of the conflictive, nonsensical, and enigmatic features of emotional life, and a curiosity toward the structure of intersubjective development with stress on its most vulnerable relations. All psychoanalytic theory posits the formative power of childhood to extend, as remnants, its constitutive conflicts throughout the life cycle. It pushes curriculum theory to consider as primary the breakdown of meaning, the refusal of knowledge, the problem of censorship, and anomie in learning. Psychoanalytic theory proffers ways to understand these subjective and social processes that defend against what is most unknown and subjective in knowledge and insight.

Ego psychology evolved from Freud's change of therapeutic direction from making the unconscious conscious (id- psychology) to the analysis of ego defense and resistance to the resistance to change. The ego is the seat of anxiety and defenses against it such as ultraistic surrender, identification with the aggressor, intellectualization, denial, splitting, reversal into its opposite, idealization, and disavowal of reality. Anna Freud, whose work crosses the fields of psychoanalysis, education, and law, is known for introducing the ego's mechanisms of defense into the discussions of parents and teachers. Whereas many consider ego psychology as a psychology of adaptation to reality, a closer look at this field will reveal its contemporary transition from adaptation to questions of sublimation of instinctual life. Contemporary figures such as Erik Erikson and his work on identity crisis and society,

cultural change, old age, and his colleague Peter Blos, have shaped the field of adolescent development and teacher learning. From a different vantage, the work of Roy Schafer on narrative and psychoanalysis opens ego psychology to postmodern preoccupations with the fluidity and construction of meaning from the vantage of symbolizing anxiety and therefore working through the problem of loss.

The British object relations school begins not with the solitary ego but with the relation between infants and mothers and within its three primary developments of the theory, proffers variations on the relations of fantasy, environment, thinking, and aesthetics. Although the problem of innateness was essentially displaced from the ego to the object, this object relation theory supposed the mind as a crowded world of object relations and moved psychoanalysis from biology to psychology. Beginning with the work of Melanie Klein and her analysis with very young children, the supposition is that rather than consider the ego as beginning in pleasure, the ego always seeks objects that are introjected (taken inside) and projected (sent outside) into the world of others, first as a defense against anxiety and as a way to determine good and bad, and later as a means to repair the self/other relation. The first object is the mother's breast, which causes both frustration and gratitude. In the beginning of life, need and hunger are fused with anxiety and depression; these positions Klein named as the paranoid/schizoid position and the depressive position. Both create the mind and the desire for symbolization; both express the tension between actual other and the one hoped for. Whereas in the paranoid/schizoid position, anxiety and splitting dominate, the depressive position ushers a new kind of love and desire for reparation. In Klein's view, symbolization allows these positions their enigmas and so is created not so much from the technical work of putting things into words as it is from its own imaginative force that allows for greater abstraction, love of metaphor, metonymy, and fantasy and so a greater freedom of expression where one need not choose between reality and imagination.

A second development of object relations theory emerges from the work of Donald Winnicott, a psychoanalyst who was also a pediatrician, and in his work with infants, children, and adults, laid

stress not on the infant's fantasies, anxieties, and defenses but rather on the relation of play between mother and infant, where the mother lends her mind and subjective resources for the child to use as she or he will. The infant's destruction of these resources, he felt, were signs of hope that mother and infant could survive the fragility of being. He emphasized the maternal environmental provision: the mother's capacity for reverie and containment of the infant's ruthless qualities. Winnicott's most-known contribution to education concerns the relation between playing and reality and the measure of the "good enough mother." He defined health as the capacity to play with things, ideas, people, and the sense of the self. A third development within object relations is the work of Wilfred Bion, who moved Kleinian thought into a theory of thinking, where thinking is an apparatus for digesting thoughts and so the means to tolerate emotional pain.

Jacques Lacan and the post-Lacanian are the dominant representation of the French tradition. The theory is known for its critique of psychoanalysis with a radical return to Freud. Its theory moved away from the innateness of biology and psychology onto questions of language and culture. Feminists such as Jacqueline Rose, Shoshana Felman, and Juliet Mitchell have been central to the translation of Lacan into fields as diverse as cultural studies, literary and film studies, feminism, and social thought. Whereas ego psychology and the British object relation theory focus on the problem of loss, Lacan believed the question is best presented through the subject's lack, by which he means the division of the subject, necessary for the creation of the subject's desire for the other. And, although the work of language is the *sine qua non* of psychoanalytic practice also known as "the talking cure," with his theory of the signifier (a sound, a sign, a mark, a signal, or a word), Lacan places language and therefore difference into the heart of becoming a subject. His contribution is to open the analyst's listening to the otherness of the signifier.

Lacan brought the problem of desire to the subject's problems of autonomy, freedom, and ethics and situated desire in the gap of its structure rather than in the meaning of language. In his return to Freud, Lacan highlighted a social problem of the human: having to have language to express its

inner world and its sense of desire for others. Rather than focus on a psychical apparatus as an innate or consider psychoanalysis as developmental correction for parental failure, Lacan turned to the agent's relation to truth and knowledge. He proposed an ethic of psychoanalysis that resides in three dimensions of human life: the real, or that that is traumatic and escapes symbolization; the imaginary, or the image of a thing which supposes unity, wholeness, and completeness of both ego and other; and, the symbolic or the dimension of law and language that awaits the subject and constitutes it through lack, demand, and desire.

Felman's writing on Lacan, so influential in curriculum theory, presents a style of teaching—the teacher teaches the ways in which she learns and so teaches both a relation to knowledge and to what she does not know. Counterintuitively, learning is learning one's ignorance. Perhaps more than any other psychoanalytic theory, Lacanian thought provides education with a new understanding of its discourses, or linguistic structures, from which to understand what it is that we do with our lack in the name of knowledge, desire, and the other's demand. The interest is not in better knowledge but rather in opening the subject to the enigmas, paradoxes, and truth of her or his desire. The road is littered with obstacles fused with the subject's wish for completion. Lacan moves discourse away from communication and into its signifiers and problems of misrecognition. He argues that understanding is not a punctuation of knowledge but a desire. Yet the teaching is difficult because Lacanian thought leans on algebraic symbols, made to loosen anticipatory knowledge that closes the subject inside the prison of certainties. Thus, in Lacanian thought, learning may be defined as the capacity to be surprised by what one does not want to know.

### Literacy and Psychoanalytic Theory

Psychoanalytic theory is an index of what the social excludes. It would thus be curious about censorship, gaps in memory, fear of ideas, and symbolic impoverishment. Given that any curriculum presents signifiers of learning and ignorance, psychoanalytic theory may be approached as positing, inviting, and rectifying our original literacy. Learning to freely associate with this paradoxical

theory, which in fact may question why we have theory at all, requires a revision of knowledge, an open mind, and an ongoing curiosity about why we feel we must shut up.

## PUBLIC PEDAGOGY

---

Public pedagogy is a theoretical construct focusing on various forms and sites of education and learning occurring beyond formal schooling practices; in institutions other than schools, such as museums, zoos, libraries, and public parks; in informal educational sites such as popular culture, media, commercial spaces, and the Internet; and in or through figures and sites of activism, including “public intellectuals,” grassroots social activism, and various social movements. Public pedagogy theorizing and research is largely informed by the contributions of cultural studies; accordingly, public pedagogy is concerned with both the socially reproductive and counterhegemonic dimensions of pedagogical sites that are distinct from formal schooling. In taking up curriculum studies' core epistemological question of “what knowledge is of the most worth,” public pedagogy interprets educational institutions as fluid, open systems that are themselves nested within multiple, overlapping, and contested sites of learning. Public pedagogy research thus investigates social contexts for informal pedagogical practices that

advance either dominant oppressive structures or possibilities for democratic resistance and reconfiguration, yet much of the work that has occurred focusing on the public pedagogy of popular culture, in particular, has focused mainly on its hegemonic aspects. Multiple and distinct articulations of public pedagogy exist within the literature, with various scholars emphasizing its feminist, informal, critical, performative, and activist dimensions. Additionally, some strands of public pedagogy inquiry seek to broaden and deinstitutionalize conceptualizations of teaching, learning, and curriculum across the discipline of education.

### **Feminist Constructions of Popular Culture and Everyday Life as Public Pedagogy**

Early conceptualizations of public pedagogy originated in the 1990s with feminist theorists' efforts to understand popular culture and the practice of everyday living as sites of pedagogy. Carmen Luke conceptualized public pedagogy in these ways in her 1996 edited volume, *Feminisms and Pedagogies of Everyday Life*. In this text, authors addressed how gendered identities are constructed and circulated through a variety of sites and activities that constitute "everyday life," as well as how these identities are negotiated by individuals within these various sites. Contributors to the book focused on popular culture-based sites, such as computer games, comic books, magazines, billboards, television, children's toys, parenting magazines, and food marketing, examining how identity formation is connected to the ways in which gender, family, childhood, parenting, and mothering are represented and reproduced. Luke advanced the project by envisioning public pedagogy in a broader way that moves beyond popular culture, explicating everyday life itself as a pedagogical project. Thus, even though including popular culture as a site of pedagogy, she also includes other arenas of public pedagogy, including women's friendships and parenting. This strand of everyday-practices-as-public-pedagogy has been taken up in more recent work, including Bryant Keith Alexander's research on the performative act of buying condoms and Andrew Hickey's work on the street as a discursive site of learning.

Working within a feminist politics of ethics, curriculum theorists Jeanne Brady and Audrey

Dentith theorized public pedagogy in the mid- to late 1990s as a curricular notion oriented toward subverting dominant ideologies. Regarding media as a predominant site in which identities are constructed and aware of the processes of hegemonic cultural reproduction inherent within media representations, Dentith and Brady assert that media localities also carry the potential to serve as pathways for liberatory discourses and the (re)creation among women and other marginalized populations of collective identities oriented toward activism for justice. Requiring critical examination of daily experience and the complex interactions of government, media, and popular culture, public pedagogy creates sites of struggle in which images, discourses, canonical themes, and commonly accepted understandings of reality are disputed. Dentith and Brady thus express explicit interest in public pedagogy as a grassroots and communal phenomenon situated beyond institutional structures that fosters movement from positions of social inequality to ones of informed activism by pursuing concrete advances in neighborhoods, health and social services, education, and basic human rights.

### **Informal and Formal Institutions and Public Spaces as Sites of Public Pedagogy**

Scholars in a broad range of fields including education, anthropology, communications, performance studies, history, and even some of the sciences further widened the meaning of public pedagogy to include other informal yet institutionalized sites of learning—which are not necessarily "popular culture"—as spaces of learning, including museums, public monuments, cemeteries, public parks, and so on. This work is sometimes, though not always, informed by the theoretical constructs of cultural studies; however, other scholars working in this area embrace diverse theoretical perspectives, including a/r/tography, postcolonialism, and queer theory.

As Elizabeth Ellsworth argues, learning occurs in diverse sites and modalities, in ways that we may not consider "pedagogy" for lack of a broader understanding of that word's implications and possible meanings. Within these formal and informal sites, learning often takes on a more subtle, embodied

mode, moving away from the cognitive “rigor” commonly associated with educational experiences. Scholars who focus on sites of learning explore and explicate these sites, their formation, and their role in developing people’s relationships to their world and lives. This work focuses, for example, on the public pedagogies of art installations (see the work of Elizabeth Ellsworth, Stephanie Springgay, Debra Freedman, and Rita Irwin), museums and ethnographic collections (see the work of Craig Kridel, Lisa Lee, Tony Bennett, Elizabeth Ellsworth, Brenda Trofanenko, and Crain Soudien), industrial and educational films (see the work of Ronald Greene), historical monuments (see the work of Peter Carrier), film and video exhibits (see the work of Karyn Sandlos), 19th- and early- 20th-century fairgrounds (see the work of Kathryn Hoffmann), cemeteries (see the work of Elizabeth Yeoman), performance art (see the work of Stephanie Springgay, Debra Freedman, Bryant Keith Alexander, and Vivien Green Fryd), and performance ethnography (see the work of Norman Denzin).

### Critical Constructions of Public Pedagogy as Reproduction and Resistance

A more widespread usage of public pedagogy was developed by Henry A. Giroux, who popularized the linkage of public pedagogy with the study of popular culture, a strand of public pedagogy scholarship that has, in various forms, dominated the field since the mid-1990s. Giroux perhaps most clearly articulates his utilization of cultural studies and public pedagogy in his discussion of the relationship between culture and politics in the essay “Public Pedagogy as Cultural Politics: Stuart Hall and the ‘Crisis’ of Culture.” Rejecting right- and left-wing theorists who criticize inquiry into culture as tangential to any real humanist or political curriculum, Giroux instead takes up Stuart Hall’s notion of culture as central to political discourse. Giroux argues that inquiry into culture provides theorists with a possibility for locating political agency within totalizing institutional structures; however, this possibility is both made remote and consistently obscured by the pedagogical, hegemonic moves of culture, which collectively provide a limited, normalized language and imagination for political citizenship. In his early work, Giroux provided specific examples of popular culture’s

hegemonic pedagogy through his analyses of Disney, and films such as *Fight Club*, *Ghost World*, and *Dangerous Minds*. Other scholars took up this strand of work, producing critical analyses of popular culture sites such as Barbie (see Shirley Steinberg’s work), McDonald’s (see Joe Kincheloe’s work), and Oprah (see Janice Peck’s work).

However, curriculum scholars such as Jennifer Sandlin, Jennifer Milam, Jake Burdick, Michael O’Malley, and Glenn Savage, among others, have argued that scholarship focusing on the public pedagogy of popular culture should expand beyond what Savage calls the “enveloping negativity” that surrounds much work on public pedagogy and should try to explore more resistant forms of public pedagogy. Taking up this call, researchers interested in popular culture as public pedagogy have begun to focus more attention on the ways in which popular culture acts as a terrain of contestation and have explored the notion of cultural resistance—or resistance within the realm of culture—as public pedagogy. Although some researchers use the term “public pedagogy” to refer to such resistance, others use the term “*critical* public pedagogy,” explaining that they seek to move past the focus on the reproductive aspects of popular culture and are explicitly conceptualizing popular culture as site where hegemony is fought against, and are framing popular culture as a critical and emancipatory pedagogy. John Weaver and Toby Daspit, for instance, urge curriculum scholars to pay more attention to alternative readings of popular culture texts in an effort to uncover the more provocative and resistant uses of popular culture. Scholars who take this route focus on how popular culture operates as an arena of resistance. Through a focus on resistance, they thus seek to expand the concept of *critical* public pedagogy as it specifically relates to the ways in which cultural resistance located within the realm of popular culture can be a force for progressive social change (e.g., see the work of Kevin Tavin, David Darts, Robin Redmon Wright, and James Gee and Betty Hayes).

Giroux began to move beyond solely examining popular culture, per se, and began examining the broader culture of neoliberalism as public pedagogy, examining hegemonic aspects of the culture of neoliberalism such as ways that militarization operates as a public pedagogy using Humvee, paintball, and armed services recruitment advertisements

to reinforce a military aesthetic linked to performances of hypermasculinity. The overarching concern of this strand of Giroux's work is the articulation of the global, extensive operation of neoliberalism as a public pedagogy that reproduces identities, values, and practices, all under the sign of the market.

To counteract this hegemonic culture of neoliberalism, Giroux proposes the possibility of educators and other cultural workers as oppositional public intellectuals acting collectively to create critical, democratic public spaces that engage and transform social problems. This radical public pedagogy conceptualizes public intellectuals as educators, community activists, actors, public health employees, journalists, and others who work within institutions and informal sites of learning to counter hegemonic constructions and to advance democratic transformation. Giroux's understanding of public intellectuals and intellectualism largely centers on the Gramscian and Saidian discourse that he employs throughout his writing. In this position, the role of the intellectual is established as a critical response to the pervasive and predatory culture that emerges from media and political discourse. Giroux's figuration of the intellectual—related in his eulogy for Edward Said—however, still is an artifact of the institution, a construct of and from the academy, gifted with the capacity to somehow stand apart from culture and reinscribe its meaning. Said's metaphor of the exile then becomes a central figure in the work on public intellectualism—a figure who transcends the discursive boundaries of public and academic spheres, and in doing so, is no longer “at home” in either.

### Public Pedagogy as Performative Social Activism

Giroux's emphasis on the public intellectual as a key site of contestation against neoliberal ideology has been reconceptualized toward a more communal, decentered sense of activism in recent scholarship. In advancing public pedagogy as a challenge to neoliberalism that is oriented toward democratic projects and politically engaged communities, Brady focuses on activist individuals and community groups as public pedagogues who collectively interrupt inequality in public and private institutions and within everyday practices. This

public pedagogy is framed by the strategy of constructing alternative discourses focused on alliances rather than identities and recognizes critical self-examination as integral to democratic social action. Articulating this dynamic further, Brady suggests that research efforts should take seriously the pedagogical nature of sites that neither necessarily employ nor require the intervention of an institutionally or hierarchically located public intellectual to maintain their efforts toward realizing a more just social order. Working from feminist and cultural studies perspectives, Brady explicates her conceptualization of performative and activist public pedagogy through analysis of the *Guerrilla Girls* project, self-identified as a group of anonymous females who work to expose sexism and racism in politics, art, film, and culture at large through activist interventions within public space. Dentith pursues similar themes in her study of how girls and young women growing up on the Las Vegas strip negotiate and resist a prevailing tenor of exploitation based on gender and sexuality. A growing number of curriculum studies scholars are exploring the performative and activist dimensions of public pedagogy as possibilities for advancing democratic projects, and in so doing continue to locate the public intellectual in grassroots collective alliances formed beyond defined institutional roles and structures. Examples include Sandlin and Milam's study of the anticonsumerist activist interventions of Reverend Billy and the Church of Stop Shopping; O'Malley's exploration of Chilean secondary school students' strike for educational equity; and Donyell Roseboro, Michael O'Malley, and John Hunt's study of the pedagogical possibilities of organized parent resistance to educational inequity in the East St. Louis, Illinois, School District; and Brian Schultz's work with Chicago students-turned-neighborhood-activists.

### Public Pedagogy's Contribution to Educational Inquiry

Beginning largely with Ellsworth's 2005 book, *Places of Learning*, public pedagogy research and theorizing has been conducted with a conscious effort to extend commonplace notions of learning, curriculum, and pedagogy as a means of illustrating the limitations of educational research and theory's sole focus on schools as the epicenter of

educational activity. Ellsworth's work illustrates the ways in which public sites, by the power of their materiality, act as pedagogies that inform or are informed by the body and the affect, rather than the cognition. One of Ellsworth's key examples of this species of learning is illuminated in her discussion of the Washington, D.C., Holocaust Museum's architecture as itself a pedagogical element of that space. The extension of pedagogy in this manner is made to draw attention to the reduction of "learning" to a common set of practices and performances that typically occur in school and to broaden educational scholars and researchers' conceptualization of what *counts* as pedagogy in the greater field of culture. Curriculum studies scholars have taken up this work as a means of connecting public pedagogy inquiry's interests and positions to the broader considerations of educational research. For example, Burdick and Sandlin call for a nonreductive research ethic that resists simply translating critical public pedagogy into the discourse and criticism of the academy and the institution of schooling. They argue that such practices subvert researchers' ability to convey and promote pedagogical practices that differ radically from the known and knowable world of schooling and potentially diminish public pedagogies and intellectuals' transformative potential. In this manner, public pedagogy inquiry, coupled with Giroux's approach of integrating cultural studies into the study of pedagogies, could provide curriculum and educational scholars with new ways of understanding their practice, both within and outside traditional schooling.

## PYGMALION EFFECT

---

The Pygmalion Effect, also known as the self-fulfilling prophecy, signifies a positive impact in the field of curriculum studies and raises the issue of whether high educational expectations by school personnel (i.e., teachers, staff, and administrators) and school partners (i.e., parents/guardians and others in the community) make the outcome of student success in school more likely to occur than would otherwise have been true. The term, *Pygmalion Effect*, as it relates to schooling, was coined by the Harvard psychologist Robert Rosenthal and the elementary school principal Lenore Jacobson in their book, *Pygmalion in the Classroom*, published in 1968. The implications of their study, which took place in a low-income San Francisco neighborhood, suggest that compensatory education needed to be centered on the induction of positive expectancies in teachers where there previously existed negative expectations.

The Pygmalion theme of *becoming educated* has regularly reoccurred in English literature. English playwright, George Bernard Shaw's play, *Pygmalion*, is probably the most familiar version of the original classical myth contained in Ovid's *Metamorphoses*. The Pygmalion Effect represents not merely an idea, but also a uniquely U.S. *mythos*: Despite our race, social class, gender, our previous experiences, and even our test scores, the road to success is ultimately paved with the power of positive thinking.

Students bring a collection of dispositions to the curriculum. Backgrounds, values, standards, linguistic codes, and worldviews of middle-class and upper-class children are often more analogous with those of the curriculum. The hidden curriculum,

namely, the socialization of oppression and sense of inferiority or defectiveness in the minds of students, underscores academic and educational evolution.

Whether consciously or unconsciously, school personnel and school partners inform students what their curricular expectations are by exhibiting thousands of cues from the language they use to the body language they communicate with. If expectations can create reality, there is an enormous incentive to have high curricular expectations of the students in school personnel's and school partner's spheres of influence. By communicating in a manner that will enable students to be their best, school personnel and school partners affect students, and it does not matter if the child is actually "smart."

Within curricular discourses, the Pygmalion Effect has been widely understood (if not practiced) by educators for decades. During the civil rights era of the mid-20th century, school desegregation activists realized that simply changing the social organization of schools and the curriculum would have little effect on the achievement of students of color and working-class poor students unless a concomitant change occurred in the minds of school personnel and school partners. Moreover, activists pointed out that disadvantaged children did not possess some problem or have some deficit that needed remediation, but that changing the attitude of school personnel and school partners toward disadvantaged children would be more effective.

The Pygmalion Effect in schooling and curriculum suggests that compensatory education needs to be centered on the induction of positive expectancies in school personnel and school partners. The notion that school personnel's and school partners' low expectations for minority students cause them to do poorly in school and the notion that the creation of a highly positive attitude about

students in the minds of school personnel and school partners causes positive effects has been widely researched. As a result of this research, interesting curricular patterns of student behavior and learning resulting from the Pygmalion Effect include students volunteering more answers, initiating more contact with their teachers, raising their hands more often, and having fewer reading problems than their low expectation peers do.

School personnel's and school partners' expectations are just one piece, albeit an important piece, of the complex cultural puzzle. That is to say, there are two sides to the Pygmalion Effect: those that are self-imposed and those that are imposed by others and these impositions can influence both positively and negatively a person's self-concept. Students should have a clear understanding that there is no question of them performing well. But we must be cognizant of the positive and negative ramifications of expectations—focusing on weaknesses will not bring out potential.

## QUALITATIVE RESEARCH

---

Qualitative research in curriculum studies, as the field of qualitative research, is highly contested with diverse traditions, complicated tensions, and irresolvable contradictions. Qualitative research, as Norman Denzin and Yvonna Lincoln state, and curriculum studies, as William Pinar contends, are interdisciplinary, transdisciplinary, and sometimes counterdisciplinary. Many researchers in curriculum studies challenge traditional ways of engaging in and interpreting curriculum research, and they choose qualitative research as a form of radical democratic practice. This radical democratic orientation of qualitative research vitalizes heated debates and complicated conversations among curriculum inquirers.

William Pinar, William Schubert, and Michael Connelly perceive curriculum studies as a diverse and interdisciplinary field replete with paradigms, perspectives, and possibilities, as Schubert described in 1986, demanding multiple understanding, and with commonplaces (teachers, learners, subject matters, and milieu), as Joseph Schwab described in 1969, acting together in educational situations. In *Handbook of Curriculum and Instruction*, Michael Connelly, Ming Fang He, JoAnn Phillion, and Candace Schlein contend that the breadth, diversity, and complexity of the field and its practical relevance are central to a wide array of educational thoughts reflected in contested curriculum theories, practices, and contexts.

In addition, another significant aspect of qualitative research in curriculum studies is the broad conception of what counts as inquiry. In 1993 in his presidential address at the American Educational Research Association annual meeting, Elliot Eisner envisioned the future of educational research and emphasized that a recognition of multiple forms of inquiry led to a broadened understanding of how to transform educational research into significant educational practice in schools and societies. Researchers engaged in qualitative inquiry in curriculum studies have not only questioned whose knowledge should be considered valid and how experience should be interpreted, theorized, and represented but also have confronted issues of equity, equality, social justice, and societal change through research and action.

### Research Traditions

Qualitative research in curriculum studies draws on a wide array of research traditions, approaches, methods, and techniques such as ethnomethodology, phenomenology, hermeneutics, feminism, rhizomatics, deconstructionism, grounded theory, case studies, survey studies, interviews, participant observation, action research, teacher research, activist feminist inquiry, self-study, life history, teacher lore, autobiography, biography, memoir, documentary studies, art-based inquiry, ethnography/critical ethnography, autoethnography, participatory inquiry, narrative inquiry, fiction, cross-cultural and multicultural narrative inquiry,

psychoanalysis, queer inquiry, and personal–passionate–participatory inquiry. Sometimes they use statistics, tables, graphs, and numbers to support the thick description, a term created by Clifford Geertz, an anthropologist in his *Interpretation of Cultures* in 1973. The main focus of the most prominent qualitative research in curriculum studies is on an in-depth exploration of the diversity and complexity of experience of individuals, groups, families, tribes, communities, and societies that are often at controversy, underrepresented, or misrepresented in the official narrative.

Before the 1970s, Schwab created three important concepts for curriculum studies: the practical, the four commonplaces of curriculum (learners, teachers, subject matter, and milieu), and two forms of inquiries: stable inquiry and fluid inquiry. Ambiguous, incomplete, and fluid aspect of inquiry that focuses on changing real-life situations and contexts, rather than on preestablished, often unfit, theories, is central to qualitative research in curriculum studies.

In the 1970s, qualitative approaches in curriculum studies flourished as the field was reconceptualized. Dwayne Huebner was the first to introduce phenomenology to curriculum studies. Huebner called for an exploration of experience of curriculum through five value frameworks: the technical, the political, the scientific, the aesthetic, and the ethical. Like Huebner, James Macdonald provoked the Reconceptualization Era, influencing generations of curriculum scholars to come. Macdonald perceived education as a societal pivotal point to explore oneself and the broader human condition in a meaningful context.

As early as 1979, drawn on John Dewey's theory of experience, aesthetics, and education, George Willis perceived phenomenological inquiry as a form of interpretative inquiry into human perceptions and aesthetic quality of human experience. Ted Aoki explored the experience of curriculum through phenomenology, poststructuralism, critical theory, and cultural criticism. In the 1980s, David Jardine further developed the phenomenological inquiry as a way to help understand the world and to change the way we live. Since the 1970s, Max van Manen has used hermeneutic phenomenological inquiry to research lived experience. Rather than rely on abstract generalizations and theories, van Manen offered detailed

methodological explications and practical examples of inquiry to demonstrate how to study human experience, evoke a sense of wonder, and make meaning of experience. Phenomenology became central to currere—a driving force for the Reconceptualization Era.

Instead of using curriculum as a noun, William Pinar and Madeleine Grumet advanced currere as a verb and as an autobiographical inquiry method to study one's experience in the past, present, and future, and the impact of social milieu on experience. Pinar and Grumet were the first curriculum scholars who linked phenomenology with autobiography. Pinar and many others further reconceptualized the field by bringing an array of educational theorists in curriculum studies and some of these theorists engaged in a variety of qualitative inquiries and critically examined social and political forces enacted on curriculum. In 1977 Paul Willis, a leading British cultural theorist, established critical ethnography to portray the experience of poor and working class youth rebelling against school authority who prepared them for working class jobs. Paulo Freire, pioneering critical participatory inquiry, explored how the oppressed Brazilian peasants liberated themselves by becoming literate through telling their own life stories. Drawing from critical theories of the Frankfurt School spanning from Karl Marx to Jürgen Habermas and Paulo Freire, Michael Apple, Henry Giroux, and later on, Peter McLaren and Jean Anyon engaged in critical and participatory inquiries to study the life in schools, communities, and societies. Elizabeth Ellsworth countered the repressive myth of critical inquirers led by critical pedagogists and advocated critical feminist inquiry that perceives curriculum, teaching, and learning as contradictory, partial, and irreducible knowledge. Madeleine Grumet and Janet Miller developed activist feminist research to study women teachers and women curriculum makers' knowledge and democratic practices.

William Watkins, building on the work of W. E. B. Du Bois and James Anderson, advanced Black protest thought and developed Black orientations to curriculum studies that focus on Blacks' experience of inequities, racism, racial subordination, oppression, discrimination, White supremacy, marginal curriculum, and practices of scientific racism. Patricia Collins, Kimberle Crenshaw, and Angela Davis used the intersection of race, gender,

and class as a framework to explore the education of the Blacks because they believed that sexism, class oppression, and racism are inextricably bound in experience.

Since the 1970s, multicultural theorists such as Geneva Gay, Gloria Ladson-Billings, and Sonia Nieto, and critical multicultural theorists such as Christine Sleeter, Peter McLaren, and Cameron McCarthy have influenced qualitative researchers in curriculum studies by bringing issues of race, gender, and class to the center of concerns in educational inquiries. Kathryn Au, Geneva Gay, Gloria Ladson-Billings, and Jacquelyn Irvine have been engaged in qualitative inquiries and have developed conceptions of a culturally congruent, relevant, and responsive curriculum for disfranchised and underrepresented individuals and groups. Jean Anyon, Lois Weis, Michelle Fine, and Laurie Olsen have brought in critical inquiry into classrooms and school-based research.

Since the 1980s, Jim Cummins has been leading a group of qualitative researchers who engage in critical inquiries into the experience of language, culture, identity, and power of marginalized and disfranchised individuals and groups. Since the 1990s, Lourdes Diaz Soto, Guadalupe Valdés, Angela Valenzuela, Chris Carger, Grace Feuerverger, Stacey Lee, Kelleen Toohey, JoAnn Phillion, Ming Fang He, and Guofang Li have been exploring the experience of language, culture, identity, and power—the key curriculum issues faced by immigrants and their children in families, communities, and schools. Many of these researchers speak the languages of their participants, hold similar ethnic, cultural, and linguistic heritages, and share similar experiences of injustice.

Since the 1980s, there has been a major transition in the field as some researchers began to study students' experience of curriculum from multiple perspectives. Frederick Erickson and Jeffrey Shultz examined students' experience of curriculum from an anthropological perspective that focuses on students' everyday life experience and its cultural contexts. As teachers of immigrant and minority students, Elaine Chan, Michelle Boone, and Cristina Igoa studied their own teaching practices with the intent to improve curriculum to meet the needs of diverse students. Sofia Villenas focused on the perspective of immigrant parents on their children's education. In the research conducted by Alison

Cook-Sather and Jeffrey Shultz, students acted as researchers or participants to explore their school experience.

Marilyn Cochran-Smith and Susan Lytle have identified five trends that characterize the teacher research movement in the United States in the past three decades: (1) teacher research and inquiry communities in preservice teacher education, professional development, and school reform represented in the works of Marilyn Cochran-Smith, Susan Lytle, Sandra Hollingsworth, and Hugh Sockett; (2) teacher research as social inquiry in the work of Gary Anderson, Kathryn Herr, and Ann Nihlen, ways of knowing in communities in the work of Hollingsworth, and practical inquiry in the work of Michael Connelly and Jean Clandinin; (3) dissemination of teacher research at and beyond the local level in the work of Hollingsworth and Sockett; (4) critique of teacher research on epistemological as Gary Fenstermacher described in 1994, methodological as in the work of Michael Huberman, and critical grounds reflected in the work of Anderson, Herr, and Nihlen; and (5) transformative possibilities of teacher research as in the works of Jobeth Allen, Marilyn Carry, Lisa Delgado, and Virginia Richardson.

In 1991, Edmond Short featured diverse forms of curriculum inquiry including conventional disciplinary forms of inquiry, interdisciplinary forms, and qualitative inquiry forms. In the same year, George Willis and William Schubert, drawing from arts and humanities, called for curriculum inquirers to reflect upon their understanding of curriculum, teaching, and learning through the influence of arts in their lives. In the 1970s, Maxine Greene brought to the field of curriculum studies her work on social imagination, the place of activism, the importance of the arts, progressive school change, the role of culture, and the meaning of freedom. Greene's work inspires generations of qualitative curriculum researchers to connect the arts to cultural diversity, to making community, to becoming wide-awake to the world, to moving beyond schooling to the larger domains of education, where there are multiple openings to possibility. In the 1970s, drawing from the works of Dewey on art, experience, and education, Eisner brought the significance of arts, aesthetic knowing, and imagination to curriculum, teaching, and learning and perceived artistic-aesthetic dimension of experience as

an enlightened eye of qualitative inquiries. For Eisner, an education that neglects the aesthetic meaning making is impoverished. In the 1980s, Elliot Eisner and Tom Barone formulated arts-based educational research as a form of qualitative inquiry in education. Arts-based research influences generations of qualitative researchers and expands an unfolding orientation to qualitative curriculum research that draws inspiration, concepts, processes, and representational forms from the arts as Gary Knowles and Ardra Cole advocate in their work since the 1990s.

Self-study in the teacher-research movement parallels the development in the life history research of Cole and Knowles and teacher lore of William Schubert and William Ayers in which the teacher is perceived as researcher engaged in deeply reflective practice to change the curriculum and the world as also shown in Donald Schön's work. Participatory inquiry, originated in Latin America, Africa, and Asia, has been closely associated with adult education and literacy movements represented by Paulo Freire, Donaldo Macedo, and Budd Hall. The explicit aim of participatory inquiry is to work with oppressed groups and individuals to empower them so that they take effective actions toward more just and humane conditions.

### A Turn to Narrative and Contested Methodologies

In response to the contradictions, diversities, and complexities of human experience, as Robert Coles called for in 1989, qualitative researchers in curriculum studies incorporate narrative, story, autobiography, memoir, fiction, oral history, documentary film, painting, and poetry into inquiries. Michael Connelly and Jean Clandinin, pioneering narrative inquiry, have developed extensive narrative research on curriculum, teaching, and learning. Narrative work can also be found in the following: Kathy Carter, Katherine Casey, Susan Florio-Ruane, and Sandra Hollingsworth in teaching and teacher education; Carol Witherell and Nel Noddings in *teaching and learning*; Freema Elbaz-Luwisch in teacher development; William Schubert, William Ayers, Michelle Foster, and Gregory Michie in teacher lore or teacher narrative; Lily Wong Fillmore and Jim Cummins in language, culture, identity, and power issues; Jill

Sinclair Bell, Chris Carger, and Guadalupe Valdés in language and culture issues; Frederrick Erickson, Jeffrey Schultz, Ming Fang He, JoAnn Phillion, and Elaine Chan in students' experience of curriculum; Grace Feuerverger, Lourdes Diaz Soto, Sofia Villenas, Stacey Lee, and Guofang Li in family and community narrative; Elaine Chan, Freema Elbaz-Luwisch, Sandra Hollingsworth, and JoAnn Phillion in multicultural teaching and learning; Geneva Gay, Sonia Nieto, Christine Sleeter, Gloria Ladson-Billings, and Jacquelyn Irvine in multicultural teacher education; Carola Conle, Ming Fang He, and Candace Schlein in cross-cultural teaching and learning; bell hooks in race, gender, and class; Paokong John Chang and Jerry Rosiek in science education; Cheryl Craig in teacher knowledge and school reform; Diane Larsen Freeman in language education; Donna Alvermann in reading; William Ayers, Patricia Ford, Gloria Ladson-Billings, and Pedro Noguera in teacher and student stories and poetry; William Ayers, Anna Neumann, and Penelope Peterson in autobiography, memoir, and fiction; Louis Smith, Craig Kridel, Brian Schultz, and Patrick Roberts in biographical and documentary studies; Gary Knowles and Ardra Cole in art including painting and poetry; Noreen Garman, Maria Piantanida, and Judith Meloy in qualitative dissertation studies; and Ming Fang He and JoAnn Phillion in life-based literary narratives drawn upon narrative or literary imagination in the works of Maxine Greene and Martha Nussbaum.

Narrative is also becoming prevalent as researchers such as Gloria Ladson-Billings, Laurence Parker, Donna Deyhle, Sofia Villenas, Sandy Grande, and David Stovall draw on critical race theory to tell hidden and silenced narratives of suppressed and underrepresented groups to counter the preconceived metanarrative represented in scientific-based research that often portrays these groups as deficient and inferior.

In the midst of divergence and convergence of research traditions in qualitative research in curriculum studies, there are emergent methodologies that move beyond boundaries, transgress orthodoxies, and build an activist movement to promote a more balanced and equitable global human condition that encourages participation of all citizens, guarantees respect, innovation, interaction, cohesion, justice, and peace, and promotes cultural, linguistic, intellectual, and ecological diversity and

complexity. Through a reflexive and reflective inquiry into one's personal experience, queer inquirers explore the contestations of the categorization of gender and sexuality because they believe that identities are not fixed and cannot be categorized or labeled. This fluid aspect of identity and sexuality connects with the work of George Lakoff and Mark Johnson on body and mind connection, Martha Nussbaum's work on literary imagination and love's knowledge, and Ruth Behar's work on vulnerable observer. This complex and fluid quality of experience influences generations of qualitative researchers in cultural studies such as Marla Morris in psychoanalysis, Patti Lather in postmodern feminist research; Pauline Sameshima in pedagogy of parallax, John Weaver in postmodern science and narrative, Greg Dimitriadis in performing identity/performing culture, and Hongyu Wong in the third space to honor the fluidity and complexity of bodily knowledge in curriculum studies.

There are emergent critical and indigenous methodologies led by Linda Tuhiwai Smith, Sandy Grande, Teresa McCarty, and Tsianina Lomawaima. Indigenous inquirers connect critical theory with indigenous knowledge and sociopolitical contexts of indigenous education to develop transcendent theories of decolonization and advocate the liberty of indigenous language and cultural rights and intellectualism. There is also an emergent form of postcolonial feminist inquiry, led by Trinh T. Minh-ha, Chandra Talpade Mohanty, Uma Narayan, Kwok Pui-lan, Gloria Anzaldúa, and Chela Sandoval, that explores various experiences endured during colonialism such as migration, slavery, suppression, resistance, representation, difference, race, gender, place and responses to influential discourses of racism, sexism, classism, and colonialism. Some postcolonial feminists engage in ecofeminist inquiry that explores the intersectionality of repatriarchal historical analysis, spirituality, racism, classism, imperialism, heterosexism, ageism, ableism, anthropocentrism (i.e., human supremacism), speciesism, and other forms of oppression.

More researchers, such as William Ayers, Gloria Ladson-Billings, Therese Quinn, Jeannie Oakes, Marilyn Cochran-Smith, Nathalia Jaramillo, and David Stovall, engage in activist and social justice oriented research in curriculum studies. Drawn on W. E. B. Du Bois's work, Edward Said, Paulo

Freire, and William Ayers, Ming Fang He, and JoAnn Phillion call this form of research personal-passionate-participatory inquiry. Researchers engaged in this form of inquiry join one another to critically reflect on experience, move beyond boundaries, raise challenging questions, transgress orthodoxy and dogma, and work with underrepresented or disfranchised individuals and groups to build a long-term and heartfelt participatory movement to promote a more balanced and equitable human condition in an increasingly diversified world.

## QUANTITATIVE RESEARCH

---

Quantitative research, in the context of curriculum studies, is defined as research about curriculum that collects and analyzes information and data that are represented by numbers. In this entry, quantitative facts, claims, and data are contrasted

with qualitative information. Research methods and designs that are commonly used in quantitative research are identified and described. The last section of the entry addresses five central concepts that are used in the design and conduct of quantitative research: internal and external validity, hypothesis testing, and reproducibility and generalizability.

### Quantitative Versus Qualitative Facts, Claims, and Variables

Research studies, whether they are described as quantitative or qualitative, involve the use of facts, claims, and variables. Facts, claims, and variables that are represented by numbers are regarded as quantitative information. Facts, claims, and variables that are presented in narrative, categorical, or nominal forms are regarded as qualitative information. In most research studies, both qualitative and quantitative information are presented and analyzed. For example, many qualitative studies include numbers to describe phenomena of interest, such as numbers of times particular events occur, time periods or dates that document when an event occurred, or the amount of time devoted to particular activities. Many quantitative studies include qualitative variables in the form of constructs that are the object of study, categories or kinds of phenomena that are being examined, or descriptions of the contexts in which the interventions take place. Thus, the distinction between quantitative and qualitative data and studies may be overdrawn.

Mixed-methods designs are used when it is important to include both qualitative and quantitative data. For example, case studies often use mixed-methods designs and include qualitative data from interviews and focus groups and quantitative data in the form of test scores, counts of behaviors that occur in settings of interest, or summarized survey data.

### Overview of Methods Used in Quantitative Research

In conducting quantitative research, several kinds of activities constitute the methodology of the study. The following section identifies and briefly describes these methods; clearly the treatment is

not exhaustive and more sources about quantitative research are specified in the Further Readings section.

Two critical activities that a researcher encounters when conducting quantitative research are the identification of the study purpose and the selection of an appropriate research design (e.g., survey, experiment, quasi-experiment). The choice of design is shaped by considerations such as the economy of the design, the strength of the inferences that can be made, and how quickly the results may be available. After selecting a research design, the researcher has to identify the population to be studied and the sampling procedure needed to conduct the study. The sampling procedures required may include determination of the size of the population, the use of a random or convenience sample, use of probability or nonprobability samples, and stratification of the population before selecting the sample. If there will be random assignment of participants to treatment and comparison groups, the researcher must establish the size and comparability of the groups to be compared. As part of planning quantitative research study, the dependent and independent variables must be identified and the instruments used to measure these variables must be developed or purchased. It is advisable to choose “off-the-shelf” instruments with established evidence of reliability and validity. However, if such instruments are not available, it is important to follow a systematic process of instrument design, development, and pilot testing. After the logistics of the data collection are complete, it will be necessary to conduct appropriate statistical analyses of the quantitative data. These analyses might make use of contingency tables, correlational techniques, regressions, analyses of variance and covariance, and more recently use of multilevel analyses, such as hierarchical linear modeling.

### Overview of Research Designs Used in Quantitative Research

Historically, quantitative data have been analyzed using a variety of research designs. The purpose of this section is to identify and briefly describe three widely used designs: experiments, quasi-experiments, and surveys.

A true experimental design is one in which participants are randomly assigned to treatment and

comparison conditions. There are three true-experimental designs—(1) the pretest-posttest control group design, (2) the Solomon four-group design, and (3) the posttest-only control group design. These designs are characterized by either the random selection or random assignment of participants (whose performances are being evaluated) to at least one treatment and one comparison group. After the study is implemented, one or more criterion measures are administered after the treatment (possibly before the treatment, as well). Differences between the treatment and comparison groups are compared to determine the effectiveness of the competing treatments. For example, a true experiment might be used to document the effectiveness of a fully developed, inquiry-based science curriculum. In this design, the new science curriculum might be implemented in a specific educational setting under ideal conditions to a set of classrooms that have been randomly assigned to receive the new curriculum. The performances of the students receiving the “inquiry-based science curriculum” will be compared with those of a group of classrooms that have been randomly assigned to the “business as usual” or standard science curriculum. The use of the true experiment will permit the researchers to make causal inferences about the effects of the inquiry-based curriculum on middle school students’ knowledge of science content and inquiry skills in the district. The true experiment is judged to be the most useful for demonstrating the impact of a program or intervention. However, to conduct a true experiment, the design must include randomization in selection of participants and in assignment of participants to treatments. The question of whether an experimental design should be used rests in large part on the feasibility of random assignment of participants to treatments. In curriculum studies, it may not be feasible for researchers to randomly assign participants to a particular curriculum or instructional program.

Quasi-experiments contrast with true experiments. Four quasi-experimental designs that are commonly used include regression-discontinuity, matched “constructed” control groups, statistically equated constructed controls, and designs that use generic output measures as controls. In quasi-experiments, the treatment and comparison groups are formed nonrandomly. For example, in a quasi-experiment, the statewide mathematics

scores of a group of 10th-grade students who volunteer to use a new technology-based math curriculum might be compared with the average statewide math performance of all 10th graders in the school. Students in the treatment group are self-selected; thus, the study, unlike an experiment, does not control several extraneous variables—students’ interest in mathematics or prior mathematics knowledge or achievement—that are likely to affect the outcomes of the program. Because many curricula are complex, the use of quasi-experimental designs supplemented by surveys and naturalistic inquiries is often the design approach of choice.

A survey design involves drawing a sample of subjects from a population of interest and administering a questionnaire or interview (or both) to make inferences about the population on the topic of interest. For example, a random sample of science teachers who implemented a particular curriculum might be drawn from the population of all teachers who used the curriculum. The survey instrument will be used to document their satisfaction and familiarity with the components of that particular science curriculum and generalized to all science teachers who had used the curriculum.

### Key Concepts in Quantitative Research

Quantitative research typically relies on the use of rigorous designs and statistical analyses to establish its findings. Five basic concepts that are central to applications of quantitative research are internal and external validity, hypothesis testing, and the importance of reproducibility and generalizability. These five concepts are described here.

#### *Internal and External Validity*

Quantitative research in all subject areas, including curriculum studies, is typically designed with considerations of external and internal validity in mind. The strength of the inferences that a researcher can draw depend on the degree to which the potential flaws in study design have been avoided. Threats to the internal and external validity of the proposed quantitative study must be considered. *Internal validity* refers to the extent to which the results of a study, often an experiment, can be attributed to the “treatment” or “intervention”

rather than to limitations and flaws in the research design. Another way to express this is the degree to which one can draw valid conclusions about the causal effects of one variable on another. The internal validity of a study is often described in relation to the study's external validity. *External validity* is defined as the extent to which the findings of a study are relevant to subjects and settings beyond those in the study—another term for this quality is generalizability. True experiments have strong internal validity, but this advantage may come at the cost of lower external validity, which is one reason why the curriculum researchers may choose to use quasi-experimental designs.

The decision about whether to use an experimental design has to address the issue of whether there is adequate power in the design to detect the effect of the treatment. Another key issue is treatment-related attrition, such that the initial comparability of treatment groups achieved through random assignment is lost by the end of the study. In cases where differential attrition occurs, a non-equivalence may result that may be the true reason for any significant differences in outcomes. Thus, the research needs to plan analyses to discount the possibility that treatment-related attrition has occurred.

### *Hypothesis Testing*

Hypothesis testing is the classical approach to evaluating the statistical significance of quantitative research findings. The approach permits an empirical comparison of observed findings from the study sample with findings if the null hypothesis were true. Hypothesis testing allows the researcher to compute the probability that the observed outcomes could have been caused by chance alone.

For example, a researcher might study the effects of a calculus curriculum that uses simulations on the performance of high schools students compared with the performance of students in a calculus class that did not use simulations. Fifty 10th-grade students volunteer to participate in a summer school program to learn calculus. The researcher assigns them randomly into two groups: those who will use the calculus with simulations curriculum and those who will use the calculus curriculum without the simulations. The researcher provides the students with a large number of

calculus problems to solve and records the number they get correct in a given amount of time. The research hypothesis is that students who used the calculus curriculum with simulations would be more efficient and accurate in solving the problems than their counterparts would be.

To test the research hypothesis, the researcher tries to find evidence that allows the null hypothesis of no difference between the groups to be rejected. The empirical data is examined and the difference between the observed mean values on the calculus test is obtained. The researcher then asks, "What is the probability of observing a difference equal to or greater than the one obtained by drawing samples at random from the groups involved, when it is assumed that the null hypothesis is true? If the probability is small, the researcher may reject the null hypothesis; if the probability is not small, then the researcher must conclude that the observed difference in the average test scores of the two groups could be accounted for by variations in sampling in the two groups. If the researcher rejects the null hypothesis, then the alternative hypothesis may be accepted. This implies that the observed difference between the average calculus test scores of the two groups is a result of the calculus curriculum that incorporated simulations. Statistical inferences about performances are based on hypothesis testing and are fundamental to the conduct of quantitative research.

### *Reproducibility and Generalizability*

A key purpose of many research studies is to arrive at valid inferences about whether an intervention or program is producing significant net effects in the desired direction. Quantitative data, which can be collected systematically and uniformly, are more likely to yield relatively precise estimates of such effects. The validity of inferences about the phenomena or effects being examined in such studies is strengthened when the findings are reproducible and generalizable.

The reproducibility of a research study depends on the research design. If the research design produces findings that are sufficiently robust, another researcher using the same design in the same setting and keeping the essential features of the study intact, should achieve about the same results. To reproduce findings, the research design has to have

sufficient statistical power and a sample size large enough to detect effects, the intervention or treatment has to be faithfully implemented, and the statistical models used to analyze the data have to be appropriate. Studies that meet these conditions are likely to produce similar results regardless of who conducts the research. Thus, a randomized, controlled experiment is likely to produce reproducible outcomes, whereas study designs that are cross-sectional, or rely on qualitative judgments, or have an intervention that is not structured and difficult to faithfully implement, are less likely to be reproducible.

Repeating studies using different individuals or different settings is valued because it increases the external validity of the findings. Generalizability is defined as the applicability of the research findings about the program being examined to related programs or settings. When considering the generalizability of a research design, several issues need to be considered. For example, the target participants of a particular program should be an unbiased sample of the participants who will use the program. Thus, if a researcher is studying the effectiveness of a U.S. history curriculum for use with regular high school students, then it should not be studied using a sample of only gifted students. A curriculum that works well with gifted children may not confer the same benefits on students with less ability. Another aspect of generalizability to be considered involves unintended variations in the program caused by the quality of implementation. For example, a program being studied must be a faithful reproduction of the program as it will be implemented. Dedicated and informed researchers who possess substantial information and commitment to a particular curricular program will implement the program differently than will the classroom teachers responsible for implementing the program in a large, urban school district that has few resources to support its teachers. For results of quantitative studies to be generalizable, they must be faithful to programs and tested with individuals that are truly representative of their intended use.

## QUASI-EXPERIMENTAL RESEARCH

---

Quasi-experiments are research experiments that involve interventions or treatments, have criterion or outcome measures, and units (e.g., participants, classrooms, schools). However, unlike true experiments, quasi-experiments do not make use of random selection or assignment to create the comparisons that will be used to infer that treatment-caused changes have occurred. Rather the nonequivalent groups that are compared in quasi-experiments are likely to differ in many ways other than the particular treatment whose effect is being examined. To separate the effects of the treatment from those due to the noncomparability in the groups is the challenge the researcher faces. Quasi-experiments are particularly important to the field of curriculum studies as the impact of a particular curriculum on student outcomes often has to be studied in complex field settings, which makes the conduct of rigorous true experiments difficult. Therefore, when studies of curriculum are needed, it is often quasi-experiments that are the research design of choice. In this entry, the logic behind quasi-experimental designs is set forth, four kinds of threats to the validity of quasi-experiments are described, several types of quasi-experiments are introduced, and implications are drawn about the use of quasi-experiments in curriculum studies.

### Logic of Quasi-Experimental Designs

A quasi-experimental research design is intended to approximate a true experiment in real-world settings where complete control or manipulation of some variables is not possible. The critical distinction between true experiments and quasi-experiments is that the units being evaluated are not randomly selected or assigned. An example of a study that cannot construct groups randomly is found in cases when all individuals who meet the eligibility criteria for a social program are required to receive the program. This situation occurred in some evaluations of the Head Start Program, which was targeted at preschool children from low-income families. In many local Head Start Centers, all of the children who met the eligibility criteria were enrolled in the program, which eliminated the possibility of randomly assigning some eligible preschoolers to a control group. Another example occurs when all students performing below a specified proficiency level on an assessment are required to take a remedial course or curricular program. When control groups cannot be formed randomly, there are likely to be several threats to the validity of the causal inferences that can be drawn between the treatments or interventions and the outcomes. Less confidence is placed on the inferences drawn from quasi-experiments than on inferences drawn from true experiments. However, quasi-experiments are more flexible than true experiments and can be more easily implemented in field settings, thus, the results of the studies are often more generalizable. These qualities suggest that quasi-experiments are likely to be a desirable choice for use in curriculum studies.

### Threats to Validity

The identification of threats to the accuracy of causal inferences between treatments and outcomes in experiments and quasi-experiments was a significant advance in the social and behavioral sciences. Initially, researchers focused on issues of internal and external validity. Internal validity refers to the confidence the researchers have that the study findings are attributable to the treatment alone. When the researcher can eliminate rival hypotheses that might produce the observed relationship, the internal validity of the study is

strengthened. External validity has to do with the generalizability of the study findings to other populations. Quasi-experiments vary in the degree to which they limit the internal and external validity of the studies. Over time, the kinds of validity that could threaten the inferences drawn from experiments and quasi-experiments were expanded to include statistical conclusion validity and cause and effect construct validity. However, experts in research design do not agree on that so many types of threats to validity are valuable.

### *Internal and External Validity*

Threats to internal validity include history, maturation, testing, instrumentation, statistical regression, selection, mortality, interaction of selection with maturation, history and testing, ambiguity about direction of causality, diffusion of treatments, compensatory equalization of treatments, and demoralization of respondents in groups not receiving the treatment. Researchers need to consider to what degree the quasi-experimental design they propose to use covers these threats. For example, if there are differences in study participants before receiving the intervention, then there is a threat to the internal validity of the study. The difference between the treatment and control groups might be explained not by the interventions, but by the prior differences. If different individuals scored the pretests and the posttests, the difference in the performance of students from pretest to posttest may not be a result of the intervention, but result from the change in personnel scoring the outcome measures. There are numerous threats to internal validity, and they each need to be considered during the design of the quasi-experiment. Not all the threats can be eliminated, but they can be reduced.

Threats to external validity include interaction of selection and treatment, interaction of setting and treatment, and interaction of history and treatment. Basically, the researcher asks if the treatment can be generalized beyond the group studied. The researcher has to determine if the cause and effects that are being studied in the quasi-experiment can be generalized across individuals, locations, learning settings, and occasions.

Overall, in identifying threats to internal and external validity, the researcher's goal is to choose

a design that minimizes the effects of extraneous factors that might make it difficult to interpret the effect of the treatment.

Replication of the quasi-experiment can improve the validity of the findings by permitting the effects of a treatment to be examined over time. Thus, the use of replications strengthens the extent to which the findings about the treatment's effects can be generalized.

### *Statistical Conclusion Validity*

Statistical conclusion validity is another type of validity that researchers consider when designing experiments and quasi-experiments. Determining whether a causal relationship exists between an independent variable (presence of treatment) and a dependent variable (outcome measure) is the central focus of internal validity. This relationship is typically quantitative and depends on statistical evidence. The researcher is concerned with whether the study was sufficiently sensitive to be able to detect covariation in the variables. Threats to statistical conclusion validity include low statistical power, violated statistical assumptions, error rate, reliability of measures, reliability of the treatment implementation, random irrelevancies in the setting (environmental effects), and random heterogeneity of respondents (characteristic of participants correlates with the dependent variables). If the size of the sample is small, it becomes difficult to detect a statistical effect.

### *Construct Validity of Cause and Effects*

A fourth type of validity that is considered is the construct validity of cause and effects. After a causal relationship has been established between the independent and dependent variables, it is important for the researcher to be certain that the theoretical or latent constructs that were measured are correct. Merely labeling or calling an observable variable by the name of the theoretical construct it is intended to measure is insufficient. Establishing construct validity is a complex activity. The idea is to be able to claim that the variables being measured extend beyond the particular operational definition used in the study and represent a more abstract construct. Thus, the researcher is interested in ascertaining to what other individuals,

settings, and occasions the variables apply. Threats to the construct validity of cause and effects include poor definitions of constructs, measurement of a single dependent variable, measurement of the dependent variable using only one method, hypothesis guessing, evaluation apprehension (fake well to make results look good), experimenter expectancies, all levels of a construct are not well implemented (confound construct and the level of a construct), interaction of different treatments, interaction of testing and treatment, and restricted generalizability.

## **Types of Quasi-Experimental Designs**

Many study designs consist of nonrandomized quasi-experiments in which comparisons are made between groups created by participants who volunteered or were administratively selected to partake of a particular program or treatment and nonparticipants who are comparable in critical ways to the participants. Although both groups are compared, the groups are not formed using the randomizing procedures required for true experiments. Four types of quasi-experiments that are widely discussed include matched "constructed" control groups, statistically equated constructed controls, interrupted time series, and regression-discontinuity designs. The first three types are frequently used, but regression-discontinuity is more difficult to implement and is not as widely used as the others, though it has qualities that make it a desirable research choice, if possible.

### *Nonequivalent Control Group Design*

The most commonly used type of quasi-experiment has been the nonequivalent control group design. Within this type of design, the variant referred to as "nonequivalent control group design with a pretest and posttest" has been, by far, the most popular.

As with all quasi-experiments, a researcher needs to be aware of the threats to validity that are associated with the design being implemented. In the case of the "nonequivalent control group design with a pretest and posttest," the greatest sources of invalidity in this design are differential selection, differential statistical regression, instrumentation, the presence of differential growth

rates among the participants in the two groups, the interaction of selection and history, the interaction of pretesting with the treatment and the interaction of any group differences present during selection with the treatment.

### *Interrupted Time Series Design*

Several quasi-experimental designs involve multiple measures of outcomes both before and after an intervention. Such designs are like the nonequivalent control group design except that several pretest and posttest methods are present. With several pretest measures, the reliability of the baseline data is greater and when several posttest measures are taken, one can determine the sustained effects of the treatment. This type of interrupted time series can be valuable in determining the long-term effects of various curricula. The primary threats to designs of this type are history, instrumentation (if it follows directly on the treatment), the interaction of testing at various points with the treatment, and the interaction of the dissimilarity in the groups (nonrandom selection) with the treatment.

### *Regression Discontinuity Design*

Within the class of quasi-experiments, the regression-discontinuity design is the closest to the randomized experiment in its ability to provide unbiased estimates of the effects of an intervention. These designs provide an opportunity to detect whether the treatment group shifts on an outcome measure, compared with a group of untreated individuals, holding constant the factors that resulted in their placement in the treatment group. The application of the design requires that individuals be selected for membership in the intervention using rules that are precise and uniformly administered. Outcome measures must be valid and reliable. If these criteria are followed, the effects of the program or intervention can be detected statistically by examining the performances of individuals who are at the cutting points used in the selection process. Although the rigor of this quasi-experiment is greater than others, it has limited applicability because few programs select participants in such a careful manner. In addition, the statistical analyses that are required to analyze the data require high levels of expertise.

## Implications for Use of Quasi-Experiments in Curriculum Studies

Researchers designing studies of curricula face the same decision-making processes as all behavioral and social scientists. The practicing researcher first needs to establish the following: (1) Is there a relationship between the independent (treatment) and the dependent (outcome measures)? (2) Is the relationship between the variables causal? Did one variable affect the second or would the same relationship have occurred in the absence of any treatment? (3) If the relationship is likely to be causal and proceeds from one variable to the other, is there evidence that the variables measured are cause and effect constructs? (4) How generalizable is the relationship among individuals, settings, and occasions? These four concerns are closely associated with the four types of validity addressed earlier. Statistical conclusion and internal validity are addressed in concerns 1 and 2. Construct and external validity are addressed in concerns 3 and 4. All four concerns have to be addressed regardless of the research topic or whether the researcher is designing an experiment or quasi-experiment. The primacy of issues of internal validity applies to researchers whether their focus is theoretical or applied. For the curriculum researcher, the fundamental question is likely to be whether the treatment or curriculum as implemented had the desired effect (e.g., increased achievement in the subject area of interest), thus, issues of internal validity are important.

The decision to conduct a quasi-experiment rather than an experiment is often driven by the inability to implement the “very best” design. For example, it is well known that in some circumstances carrying out a randomized experiment with students in an educational setting is nearly impossible for ethical and practical reasons and a less powerful, quasi-experiment needs to be conducted. Time and resources also limit design choices. Often the best design is the costliest. The choice about whether to do a quasi-experiment or an experiment is also shaped by the importance of the program being examined. If the intervention to be studied holds the possibility of affecting the stakeholder community in serious ways, then there is an argument for applying a more rigorous design. The choice always includes trade-offs, and there is no

single perfect design approach. Curriculum researchers are likely to find it a challenge to gain and maintain access to research populations in educational settings, formal or informal. Thus, using random assignment and withholding a valuable resource, such as a new curriculum from a control group, is not likely to occur. Quasi-experiments may be the best possible design from a methodological point of view, given the practicality and feasibility of available designs. For the curriculum studies researcher, the choice of a quasi-experiment may be the best research investment for producing both useful and credible results.

## QUEER THEORY

---

The aim of queer theory is to destabilize symbolically and materially based notions of normalcy in regards to human relations (sexual and nonsexual) and binaries, such as heterosexual/homosexual, which foster the status quo and deny people the space to fashion their own sexualities. *Queer theory* is an academic term but has its origins in social movements that took place within the lesbian, gay,

bisexual, transgender, and ally (LGBTQA) communities, ones that attempted to remain inclusive by assuming difference as the terms for relationships and also to dissolve the dominate/subjugate hierarchies within sexuality by discomposing the logic that maintains them. Within the U.S. academic scene, queer theory emerged during the mid-1980s as a form of cultural and material criticism and has its intellectual roots in feminist, critical, and post-structural theories. Transferred to the scene of curriculum studies, queer theory has been employed to examine the very possibility of education. That is, the possibility of teaching and learning when difference is read as a disruption to the normalcy and routine of schooling. Earlier work in curriculum studies focused on destabilizing gender and sexual identity categories; examining reproduction of and resistance toward the conventions of male-to-male relations; challenging sanitized representations of LGBTQA issues, concerns, and figures; and, of course, homophobia and heterosexism within public education. More recent scholarship has interrelated queer theory with longer-standing discourses in the field, including autobiography, place studies, and questions regarding educational research methodologies, to create innovative and unique forms of curriculum theorizing, ones that attempt to intervene within dominant narratives at the crossroads of sexuality and teaching and learning.

Queer theory has provided curriculum studies with mechanisms to name and make meaning of knowledge deemed unworthy and those thoughts it finds difficult to think. Extending a key question within the field of curriculum studies (Herbert Spencer's question, What knowledge is of most worth?), queer theory has been employed by curriculum scholars to illustrate the ways in which knowledge and ignorance, far from being in opposition, are intricately interrelated with each other. Here, ignorance is not the absence of knowledge but a constitutive force that structures and authorizes what becomes intelligible and what becomes taboo. That is, what is too unsettling or too risky to think about as knowable. Therefore, knowledge (and curriculum content) is examined as an effect of ignorance—always already caught up in the politics of knowledge production—and not merely something that is discovered. To examine the interrelationship between knowledge and ignorance, curriculum scholars have investigated the

production of normalcy both within and outside of school-related discourses, and examine the relationship between those productions and cultural, material, political, and educational violence toward those ideas and persons marked abnormal or deviant. Knowledge of most worth is never neutral or natural within queer theory, and it returns us to how bodies are made to practice and the practice of making bodies. That is, it returns us to questions about how certain human relationships and forms of thought become naturalized and mundane while others become abnormal and exotic.

Whereas the terms *gay* and *lesbian* have been conceived as nouns or identities, queer theory signifies actions more than actors and the destabilization of both heterosexual and homosexual identity more than the search for an authentic sense of self within a heterosexist world. Similar to the use of curriculum theorizing in place of curriculum theory—to connote teaching and learning as continuously in the making—queer theory can be thought of as a verb that signifies something in excess of its signifier: a politics in the making that subverts and disrupts the hegemonic discourse of normalcy. The aim, however, is not to merely invert the heterosexual/homosexual binary and courageously uphold the latter term, even if only temporarily, but instead to question the stability of categories implicated in the ways curriculum studies organizes its knowledge. Of course, questions about the usefulness of queer for unsettling these frameworks are embedded in curriculum scholarship itself. For this reason, it might be more helpful to think of a multiplicity of queer theories within curriculum studies. Here queer theory is refashioned in relation to global capitalism, participatory democracy, grassroots insurgencies, generational differences, hip-hop culture, contemporary literature, and so on. It is also refashioned in relation to activism within educational communities, including the work of the Gay, Lesbian, Straight Education Alliance and National Gay and Lesbian Task Force. Whether it is intervention into academic discourse or activism within educational settings, queer theory involves re-signifying practices. That is, it symbolizes attempts by those who have been atomized because of calcified, rigid gender and sexual categories and roles to redeploy the discourse and terms that sought their subjugation.

The remainder of this entry focuses on various queer theories that are significant within curriculum studies. Although it is not possible to account for complete character of all queer scholarship, it is feasible to highlight various through-lines or tentative orientations toward queer theorizing within curriculum studies. In doing so, it is important to note that curriculum scholars continuously reinvent queer theory in unique and as of yet unknown ways, ones that reflect their intellectual dispositions and the force of the ideas under study. Here, with the ongoing reconceptualization of the field, any attempt at demarcating the ways in which queer theory has been put to use will eventually become queer as well.

### Reconceptualization of Curriculum

If queer theory has its beginnings in cultural criticism and media studies, within curriculum studies it has been put to use to reconceptualize the history of curriculum. A movement with significant implications, queer theory has offered different ways of reading and intervening within the discourses of education's past. For example, traditional research on gays and lesbians has traced the construction of homosexuality within various educational domains, from policy and psychology to curriculum and media; in essence, this research has further added nuance and detail to the discourse on gays and lesbians. Curriculum scholars have used queer theory to critique these traditional approaches for the ways they essentialize sexual identities. More specifically, queer theory is used to invert the logic of curriculum inquiry that focuses on subjugated groups outside their relationship with dominant groups. One might say curriculum scholars have queered the focus on homosexuality by examining the ways it is deployed to fabricate heterosexuality as normal. It then becomes possible, once the categories have been queered, to illustrate how homosexuality (ignorance) as a marginal concept has been used to maintain the centrality of heterosexuality (knowledge). Finally, with the categories inverted (that is, scholars have shown that the category of homosexuality is central and necessary for heterosexuality to exist), curriculum scholars have used queer theory to highlight the conditions that have made the categories of heterosexuality and homosexuality possible, including the continued

dominance of the former over the latter and their contingent nature within history. Scholars might, for example, explain how in the 19th-century sexual norms were unrelated to identity or how in ancient Greece sexual relations among men of a higher social standing were, indeed, considered quite normal. The aim is to illustrate how what is considered natural at this point in time is unique to the historical moment and subject to change. This makes it possible to discompose or queer the very terms for heterosexual/homosexual or straight/gay classifications.

When the assumed correlation between sexual activity and identity is disarticulated, it becomes possible to show how gender roles and social roles complicate identities, particularly when common sense has, in recent scholarship, assumed that sexual activity and identity make certain inevitable demands upon the other. These queer perspectives are particularly important when traditional research has repeatedly focused on the development of the terms *gay* and *lesbian* since World War II and assumed that the gay and lesbian “public” identities that exist today have their origins in the Stonewall Riots of 1969. Queer theory has exposed the logic underwriting traditional research as containing partial if not altogether problematic assumptions. More specific, queer theory has questioned the assumptions that undergird gay and lesbian research based in modernist notions of an increasingly more authentic or truer sense of self, identity development theories that reduce complex sexualities to stages, and the search for the historical truths of gay and lesbian experience. To complicate sexuality and identity and to show its contingency, curriculum studies scholars have queered norms within gay and lesbian studies through research that explores the following: (a) contemporary and historical alternate conceptions of same gender relationships, such as males or females who have affectively-inclined relationships with others of the same gender in seemingly mundane settings (involved in same gender organizations for example) and those who have sexual relationships with the same gender but do not publicly or personally identify as gay, lesbian, or bisexual; (b) understudied periods of history where same gender relationships held public status before World War II or the Stonewall Riots, such as in New York City between the late 1800s and early 1900s;

and (c) how identity and sexuality are performed in ways that challenge the idea of an autonomous self and highlight the ways identities are enacted, particularly how identity and sexuality are made and remade in different contexts.

### Alternate Interpretations of Life Histories

Not unrelated to attempts to reconceptualize curriculum history, curriculum scholars have also used queer theory to craft alternative feasible readings of life history. Similar to other queer theories, curriculum scholars who work on life history reject modernist notions of rational, autonomous subjects or theories that assume there is an underlying foundation that needs to be accessed or employ discourses that privilege synthesis over disjunction. Accordingly, curriculum scholars who use queer theory find little value in one-dimensional interpretations of historical events, seeing them almost always already interpreted through lenses shaped by heterosexism, patriarchy, and sexism, among others. Here the concern is that the search for the one correct interpretation leads to the reproduction of privileged groups, particularly because it is most often their ideas, values, and beliefs that shape disciplinary knowledge. Therefore, they focus on creating alternate interpretations of educational figures, ones that account for the uncertain, complex, and contradictory character of identity and the role both readers and actors play in constructing the meaning of the text. Perhaps four of the most important contributions queer theory has made to curriculum studies have involved questioning the agenda that drives the text, the truth embedded in the text, the author who constructs the text, and the reader who interprets the text. That is, queer theory made it possible to analyze issues of language, culture, power, and knowledge in relation to normalcy, both within and outside of sexuality respectively.

Curriculum scholars who use queer theory to study lived histories accept the innumerable forces at play in the creation of texts and attempt to reveal them rather than gloss over them. The purpose of a text depends on a series of contextual issues including the political elements at work and the knowledge available at a particular time. Similarly, textual truth depends on how authors conceptualize veracity and the meaning they make

from their reading practices. The author of the text chooses the theories that are explored, the questions asked, and ideas recorded, and also shapes the way meaning takes shape on the written page. The reader takes meaning from the text according to his or her lived experience, worldview, and systems of beliefs and values. Instead of framing gay men, lesbians, bisexuals, and transgender peoples as either deviant or normalized, life histories informed by queer theory always begins with the belief that identity is partial and contradictory and that power and knowledge are inextricably linked. In the most mundane lives and events there are queer moments just as in the most exotic lives there are elements of familiarity. What becomes possible with queer theory is the de-conceptualization of normality for people who have experienced intellectual, spiritual, or physical violence because they had been previously positioned as abnormal.

### Additional Applications

Of course, curriculum scholars have used queer theory in other ways as well. Curriculum scholars have examined the controversies surrounding the inclusion of gay and lesbian issues within the curriculum as the politics of normalcy reasserting itself. They have noted that the issue is not assimilation or further reification of what is normal and abnormal, for both of these approaches reinforce structures of knowledge that privilege some while silencing others. Instead, they ask readers to move beyond efforts at inclusion, ones that seem common to the controversy regarding what should and should not be in the curriculum, and begin to critique and challenge the various structures (cultural, political, financial, educational, and so on) that oppressive organizational practices make possible.

Other curriculum scholars have used queer theory to challenge queer scholarship itself. More specific, they have critiqued queer theory as primarily the domain of privileged White education scholars who, regardless of their biological sex or affective relations, write in language far removed from its origins in activism. Here the aim is to use queer theory's focus on destabilizing categories to shake up what authors find are problematic binaries that have developed in the very movement intended to discompose such binaries. Arguably the most important work in curriculum studies

involving queer theory has to do with scholarship on HIV/AIDS education. This work has focused on what the HIV/AIDS virus has taught us about bodies and boundaries, specifically the ways in which bodies are less discreet entities than porous, inter-related, and connected across time and space. These scholars are interested in what vulnerability might mean for new ways of thinking through intersectionality and subverting us/them positions and scenarios. Others have used queer theory to examine youth politics, particularly the site of adolescence as contested and provisional, a site of debate. Because such a site is contested, it must be studied as a place of learning where youth both reinforce and contest the mainstream adult world through their bodies, languages, and cultures. Following the same lines of thought curriculum scholars have used queer theory to examine media images of LGBTQA people. Of particular interest has been the ways these representations desexualize same-gender male relationships to make them more palatable while oversexualizing female-to-female relationships, presumably to fulfill the desires of straight male audience members. Not to be overlooked, these studies of media images have explored the ways in which gay and lesbian representations have been used as tools to enhance and recenter heterosexual characters and relationships.

### Queer Theory in Curriculum Studies

In closing one might ask, what is queer theory in curriculum studies? It is the effort to decenter, eroticize, and establish relationships between bodies of knowledge and knowledge of bodies in ways that disarticulate the binaries that lead to atomized or dejected identities. The concern is not with filling out the history of gay and lesbian experiences or establishing identity development models in ways that translate the normalcy of heterosexuality into gay and lesbian communities. For queer theorists, these efforts at assimilation just will not do. Instead, queer theory attempts to discompose the binaries themselves—straight/gay, normal/abnormal, healthy/sick—through a range of mechanisms that attempt to queer what is thought to be normal or natural. The strategies might include highlighting the inability of categories to hold, such as the queer character of many heterosexually identified activities. It might also involve offering

alternative feasible readings that queer straight histories and historical figures. Indeed, the possibilities are many. In curriculum studies, if one is willing see the irony in identifying themes, queer theory has involved studies of ignorance, limits, and untold histories.

## RACE RESEARCH

---

The multiculturalists have brought race research center stage in the field of curriculum studies. They argue that the U.S. experience is not exclusively European. They have demanded rethinking and redoing of the texts, the pedagogy, and the power arrangements of schools and classrooms. Exclusion and hegemony are central to their concerns.

Race “research” has historically been dominated by those trying to establish hierarchy and genetic inferiority. Educational policy and curriculum theorizing were shaped by the early “scientific” research on race. “Justifications” of the “inferiority” of colored peoples and eugenics were sown into the school curriculum and especially the testing movement. The recent demands of urban education, civil rights, and multiculturalism have given rise to new research paradigms. Race research cannot be examined apart from its sociopolitical, economic, and cultural context. Slavery, mercantilism, and the conquest of subaltern people coincided with the “scientific revolution” in the Western world. The new scientism demanded research and quantification. As Darwinism generated interest in biological study, natural scientists, anatomists, biologists, physicians, anthropologists, ethnologists, social theorists, and politicians turned their attention to race study. If “proof” could render Whites superior, colonial plunder could be justified. The entry explores the history of race research and its influence on education and curriculum studies, especially with regard to defining and measuring intelligence.

### Scientific Racism: Early Research and Writings

Race research began in Europe. Biological taxonomist Carolus Linnaeus was among the first to classify human beings by race, claiming each exhibited different mental and moral traits. In 1781, physiologist Johann Friedrich Blumenbach added aesthetic judgments to race writing that White people are as beautiful as Mount Caucasus. In 1799, British surgeon Charles White asserted that Blacks were a separate species, intermediate between Whites and apes.

French intellectual Arthur de Gobineau is called the “father of racism.” Christian doctrine had always linked virtue with faith. Gobineau began to associate virtue with blood. Gobineau developed a notion of racial determinism claiming scientific objectivity. His *Essai sur l'inégalité des Races Humaines* (An Essay on the Inequality of the Human Races) argued the inequality of races explained all destiny and human history. His hierarchy placed the Caucasian people at the top and the Hamites or Blacks at the bottom. Miscegenation, he believed, would be the undoing of advanced civilization.

The writings of German zoologist and physician Ernst Haeckel in the mid- to late 1800s situated Blacks on an evolutionary tree below gorillas and chimpanzees. He hypothesized that each individual, in the course of its development, relives its evolutionary history, that is, ontogeny recapitulates phylogeny.

Profitable U.S. slavery and racism brought White supremacy and scientific racism across the

Atlantic. Edward Jarvis, president of the American Statistical Association, wrote in 1840 that insanity for Blacks in the North was 10 times greater than for Blacks in the South. He concluded that slavery had a salutary affect on the Blacks, sparing them the problems that free self-acting individuals faced.

Physician John H. van Evrie offered, in 1853, a “scientific” justification of slavery, positing dark-skinned people were diseased, unnatural, and possessed impeded locomotion, weakened vocal organs, coarse hands, hypersensitive skin, narrow longitudinal heads, narrow foreheads, and underdeveloped brains and nervous systems. He argued that even the animal kingdom recognized Negro inferiority and said that a hungry tiger was more likely to prey on Blacks than Whites.

In the 1850s, U.S. physician Samuel Cartwright wrote of the diseased and debased Negro possessing insufficient supply of red blood, smaller brain, and excessive nervous matter. The physical exercise provided by slavery would help increase lung and blood functions. Some slaves, he argued, were afflicted with “drapetomania,” a disease of the mind making them want to run away.

U.S. “scientific” racists included monogenists who believed there was but a single species of people originating from a single source and polygenists who claimed the human races were separate species. Both developed views of racial inferiority that fueled the emergent curriculum of anthropology and the race literature.

Respected Harvard biology professor Louis Agassiz argued the races were created as separate species differing in culture, habit, intelligence, and ability. Miscegenation was a sin against nature and would create feeble-minded offspring. He added charged adjectives and adverbs to his discussion of various race groups such as submissive, cunning, tricky, cowardly, and apathetic. Agassiz commented on the education of Black people, saying they should be trained for manual labor rather than intellectual cultivation.

Physician and scientist Samuel George Morton of Philadelphia advanced the cranial capacity thesis, that is, bigger skulls, more brains. Measuring the cubic inches of skulls from around the world he reported his “findings” in *Crania Americana*, *Crania Aegyptiaca*, and *Observations on the Size of the Brain in Various Races and Families of Man*.

Agassiz and Morton opened the floodgates for race “research.” Peter Browne’s hair “studies” in 1852 found the “canals” in White people’s hair provided “perfect hair.” Others developed the “cephalic index,” a mathematical calculation of skull ratio concluding rounded skulls were superior. French anatomist Etienne Serres “found” that belly button height variance, and flattened labias in Black women were signs of inferiority and closer kinship to apes. Internationally renowned Paul Broca, professor of clinical surgery and founder of the Anthropological Society of Paris in 1859, upheld the cranial capacity thesis long after others.

Political figures Thomas Jefferson and Benjamin Rush joined the discourse. A medical doctor and signer of the Declaration of Independence, Rush joined his interest in morality and virtue with “diseases of the mind.” He wrote that idleness, intemperance, masturbation, and sexual excess were associated with mental diseases. Rush examined the “savage” Indian given to “uncleanness,” “nas-tiness,” “idleness,” “intemperance,” “stupidity,” and “indecenty.” Opposed to slavery, his writings about Black Americans held they were pathologically infected as their coloration was disease driven. Blacks would have to be civilized and restored to morality and virtuosity through righteous living. Jefferson’s *Notes on the State of Virginia* noted that differences in the races were fixed and found in nature. A new wave of early 20th-century scientists and anthropologists argued biological determinism could not be proven, however, cultural explanations of difference remained popular.

### The Eugenics Movement

The eugenics movement advanced by Sir Francis Galton, a cousin of Charles Darwin, and Sir Cyril Burt was built on the platform of “scientific” racism. Galton’s *Hereditary Genius* asserted man’s character and capacities were primarily shaped by heredity and that the current generation shapes the future by how it breeds. Eugenics was promoted as human betterment and social reform. Purifying society has come to have a permanent place in the long-term view of refining civilization.

Eugenicists attributed poverty, ignorance, infirmities, intemperance, incompetence, “feeble-mindedness,” and criminality to genetic explanations.

Nascent U.S. eugenicists labeled the dependent, insane, ill, and criminal as genetically inferior. These eugenicists proposed restricting propagation. Organized eugenicists later advocated custodial care and sterilization as solutions for “defective” types. There existed a popular belief that Blacks were biologically moribund and would die off. People of color, (Southern) Europeans, and other immigrants became targets of eugenic discourse. Notions of human intelligence, IQ, and development were profoundly influenced by the field.

Ernst Haeckel called for the destruction of abnormal newborns. He opposed institutionalizing as it prolonged the lives of the diseased and deformed. He wanted to eliminate the lives of the “utterly useless.”

Educational psychologist and Columbia professor Edward Thorndike was a member of the Galton Society. He saw the United States in deep genetic decline composed of “robbers,” authoritarian personalities, and misfits led by a few intelligent, benevolent, impartial, sympathetic, and good people.

Eugenicists argued that their conclusions were validated by the utilization of large databases. They frequently pointed to the massive samplings in the Army Alpha and Beta tests. Princeton psychologist Carl C. Brigham in his work *A Study American Intelligence*, published in 1923, used that data in concluding Blacks were deficient in “native or inborn intelligence.”

Frederick Hoffman, detractor of Black intellectuals and educators, wrote in *Race Traits and Tendencies of the American Negro* that poverty, tuberculosis, venereal disease, and other ailments would always plague the Blacks because of their inherent immorality. Hoffman argued that no social or political reform could alter these hard scientific facts.

### Scientific Racism, Eugenics, and Testing: A Sampling of Views

Notions of difference in the social order have long been a part of the Western intellectual tradition dating to Aristotle and Plato. Measuring and defining intelligence created an industry.

French psychologist Alfred Binet understood intelligence to mean the tendency to maintain a definite direction in thinking and to make adaptation for

the purpose of a desired end. He assembled a large series of short tasks aimed at problem solving, reasoning, ordering, comprehension, and invention. David Wechsler, U.S. psychologist and architect of widely used tests, defined intelligence as capacity to act purposefully, think rationally, and deal effectively with one’s environment. W. Stern, a German psychologist, formulated that mental age should be divided by chronological age thus creating an “intelligence quotient.”

By World War I, a proliferating and interconnected eugenic and “scientific” racist movement in the United States went far beyond Binet, offering hereditarian explanations of IQ and racial hierarchy. Supporters translated heritable to mean inevitable. Racial and intellectual differentiation was presented as part of the *natural* order. These views influenced intellectual thinking, legislation, public schooling, the curriculum, race relations, and notions of social welfare. A glimpse of several central actors and their views informs us about the omnipresent discourse on IQ, heredity, and race.

H. H. Goddard insisted scores on the Binet tests represented measures of intelligence, something Binet had not intended. Goddard helped popularize the terms “idiot,” which meant having a mental age below three and the inability to master speech, and “imbecile,” which meant a mental age 3 to 7 and the inability to master writing. The “morons” were the criminals, alcoholics, prostitutes, ne’er-do-wells, and other misfits. At the highest end of the low group were the “dull.” The “dull” were blue-collar working people engaged in drudgery and uninspired labor. Goddard’s famous family “study” of the Kallikaks was an attempt to demonstrate hereditarian theses.

Stanford professor Lewis M. Terman developed the now-famous longitudinal study on hereditary intelligence. He was interested in the IQ of great leaders, past and present. Terman was also interested in identifying “high-grade defectives.” He wrote that the ability to handle mathematics was an important barometer of racial progress. Expanding Binet’s scale, Terman insisted “feeble-minded” people were disrupting society. He favored universal testing and removal of all “sociopaths” from society. Individuals in the 70–85 IQ range should be given vocational training. He and colleagues assigned IQs to people who had never even been tested.

Harvard psychologist Robert M. Yerkes administered the Army Alpha test to readers and the Beta to nonreaders. Yerkes claimed his large sample, which included prostitutes, plus the two million soldiers tested provided the data base to support his hereditarian claims. His data “showed” that African Americans scored an average mental age of 10.41, placing them at the bottom of racial groups.

Harvard professor William McDougall wrote that all personality traits were racial and fixed during the prehistoric period. He claimed Blacks were inferior, submissive, and a biological threat to the United States. He argued for a rigidly segregated society with confinement of Blacks to ghettos. McDougall feared mass participatory democracy and concocted a plan where everyone in the population would receive an identifying letter of A, B, or C. A’s would be full citizens holding the franchise. B’s would be candidates for A status, such as children; however, their attainment of A status was not guaranteed. C status meant you lacked education, were mentally defective, and to be denied voting privileges.

The wedding of “scientific” racism to Taylorist management principles created a legacy for public education. That legacy is characterized by testing, IQ designations, ability grouping, tracking, and sorting.

### **The Movement Reborn: Latter-Day Eugenicians and “Scientific” Racists**

Although eugenics and “scientific” racism have maintained adherents, they have been organizationally in disarray since the defeat of international fascism. The so-called White backlash from the civil rights movement of the 1960s had an impact at many levels. Scattered “scientific” racists across the country reopened the genetics dialogue. Dwight J. Ingle, a University of Chicago physiologist, was joined by Nobel Prize-winning engineer William Shockley of Stanford, totally untrained in genetics. Shockley began to write and speak out on “genetic defects,” “damaged genes,” “inferior strains,” and “bad heredity.”

Shockley revived the old themes of Negro genetic inferiority. He argued their poor intellectual performance was irremediable by environmental factors. The “War on Poverty” was a

Shockley target. He became an assertive supporter of sterilization advocating financial bonuses to people who would agree to sterilization. He and Ingle would soon be joined in partnership by Berkeley psychologist Arthur Jensen.

Unlike Shockley and Ingle, Jensen studied race, culture, and intelligence with Cyril Burt, the eugenicist. Jensen’s hard-line hereditarian views exploded onto the U.S. scene in the *Harvard Educational Review* in 1968. Here, he lambasted compensatory educational programs, claiming nothing in the environment can influence inherited intelligence. His catchword, like that of Shockley, was genetic “enslavement.” And he viewed those individuals with low IQs as a burden to society and to themselves.

Richard Herrnstein and Charles Murray represent more recent attempts to resurrect hereditarian arguments. Financially supported by the Bradley Foundation and the American Enterprise Institute, their book *The Bell Curve*, published in 1994, ignited a firestorm of controversy for its ideological bias and its conclusions. Herrnstein and Murray equated intelligence with the IQ test score. Intelligence, for them, was the measure of efficiency, productivity, social conduct, criminality, school success, mental well-being, and a host of other behaviors. They believed people were appropriately fitted into those slots mandated by their “intelligence.” They argued that the gap in intelligence was becoming more critical in our technological society as the demand for higher skills was intensifying. They insisted that government policies aimed at equity are wasted on people who are *forever* crippled by their mental capacities. Intelligence is equal to destiny. Natural superiority is the order of the world.

### **Race Research: New Directions in Science and Curriculum Study**

“Scientific” racism undergirded the architecture of Black education as the “naturally inferior” Black would always occupy a socially subservient position. Industrial education was promoted as right for the Blacks and they for it. It was marketed as progressive democratic reform. Mid-20th-century social movements for civil rights, school equity, social justice, and cultural understanding contributed to re-thinking race. Most biologists, although

not all, now believe that the differences between White, Black, and Brown people are no greater than the differences within those same groups. Emerging research in curriculum study removes race from the boundaries of science and biology and locates it within history, political economy, and sociology.

## RADICAL CAUCUS OF ASSOCIATION FOR SUPERVISION AND CURRICULUM DEVELOPMENT

---

The Radical Caucus of the Association for Supervision and Curriculum Development (ASCD) constituted an informal network of members who met periodically between 1970 and 1976. The intent of the group, numbering more than 100 ASCD members, was to radicalize the organization and its membership through staged “counter convention” events at the national ASCD conferences. Radical Caucus coordinators included Steven Mann, William Pildar, and Richard Kunkel, who organized planning meetings and prepared periodic newsletters and mailings. Topics of importance to the membership included the issue of student rights (and whether constitutional rights could be extended to students without drastic changes in the educational structure and school curriculum) and class

analysis in relation to educational reform. The issue of student rights was seen as a way to ascertain ASCD leadership and whether the organization would be willing to publicly censure any school system that did not tolerate students’ freedom of speech and right to assemble. The Radical Caucus also attended to women’s, racial, and men’s issues as well as to matters of “internal consciousness-raising” (defined as exploring one’s relationship to ethnic minorities, examining the extent to which individuals are political educators, and questioning why individuals associate with the Radical Caucus). A 4-day forum, sponsored by the Caucus, on class analysis and education was staged at the 1975 ASCD Conference.

Through informal discussion and newsletter correspondence, the Radical Caucus viewed itself in opposition to ASCD and specifically objected to the then-popular “humanizing education” movement, which was viewed as obscuring the administrative structures and bureaucratic commitments on which objectionable current practices were based. The group considered how it would interact with ASCD leadership and decided to define itself as a pressure group and to generate resolutions and requests to ASCD central administration, participate actively in organizational committees, and maintain a visible presence at the annual conventions, consisting of setting up information booths and selecting specific sessions as “potential worthwhile targets” to attack as a way of raising levels of consciousness.

In relation to the ASCD practice of maintaining a broad constituency of professional educators, the Radical Caucus concluded that its efforts should be oriented toward (a) building a limited yet politically active constituency of professional and non-professional educators, (b) developing public policy positions that serve to identify educators who accept traditional educational practices, and (c) enacting political strategies to challenge the power and jurisdiction of ASCD and established school systems. The *Albuquerque Connection* newsletter reported that the group agreed to work closer with the Women’s Caucus and the Black Caucus of ASCD. The activities of all three caucuses have not been examined and call for further study by today’s curriculum historians.

## RATIONAL HUMANISM CURRICULUM IDEOLOGY

---

Within professional and public sectors, many recognize the normative function of education as a deeply value-laden social enterprise by which particular visions of and values for education and human life are conceptualized and cultivated, and this, largely occurs within the curriculum. Thus, in the study of curriculum, attending to ideology—the implicit or overt system of ideas, beliefs, and values that shape a particular way of seeing and being in the world—is an enduring matter of significance. Rational humanism is one such ideology that Elliot Eisner posits informs current curriculum thought and practice. Expressing faith in the power of reason and capacity of intelligence to direct human growth and progress, this orientation has enjoyed a long history; avidly defended and opposed, and subjected to complex transformations and differing interpretations over time, it continues to exert, if only latently, an abiding influence with which curriculum scholars must reckon. The following discussion proceeds with further description of rational humanism issuing from Eisner’s analysis, entertaining key arguments for and against it, its distinguishing historical roots and routes, and some persistent questions kept alive by the curriculum commitments it bears.

Although Michael Apple, in *Ideology and Curriculum*, is best known for drawing attention to the import of ideology in directing and reproducing what is attended to and affirmed in curriculum, and educationally valued, Eisner has sought

to identify major curriculum ideologies shaping contemporary discourse and direction in the field. In Eisner’s typology, rational humanism finds its place among and in relation to the contrasting curriculum ideologies of religious orthodoxy, progressivism, critical theory, reconceptualism, and cognitive pluralism. For rational humanism, the heart of the educational enterprise is found in cultivating our humanity through the development of human reasoning (i.e., in inquiry, observation, study, questioning, dialogue, and reflection).

For educational advocates strongly allied with the ideological underpinnings of rational humanism such as Mortimer Adler, Robert Maynard Hutchins, E. D. Hirsch, William Bennett, and Alan Bloom, the selection of and emphasis on curriculum content is of utmost importance, engaging the young with that which represents the best of our cultural heritage and wealth, and artifacts of highest human achievement. The *Great Books* programs of Hutchins and Adler (in the 1930s and 1950s) and Hirsch’s *Cultural Literacy* curricula guides identifying what all U.S. children should know are examples reflecting this tenet. It is argued that for a society to be strong, for people to intelligibly converse and come together across differences on equal footing to solve shared problems, a common intellectual culture—and thus, it follows, a core curriculum, built on authentic primary sources—is required.

Proponents of this view generally oppose the provision of vocational or elective courses in grade school curriculum, such choice or specialization not unimportant but more suitably provided elsewhere. The philosophical, artistic, literary, and historical have as much place as, if not more than, those studies deemed most work-related or practical, including the scientific and mathematical. Pedagogical methods must not be didactic either, but rather provoke analysis, criticism, interpretation, discussion, and debate. Higher-order thinking is promoted by searching for evidence, articulating reasons, and entertaining oppositional views. Paramount is nourishing the rational powers of every child through engagement with the liberal traditions and disciplines—critical understandings, humanistic values, modes of inquiry, forms of discourse—that constitute the height of human knowledge.

Much of the criticism aimed at this perspective questions the criteria, and the value judgments

upon which they are based, by which what constitutes this height of human knowledge is determined. Traditionally wed to human works and forms of understanding of Western civilization, rational humanism has been accused of endorsing education and constructing curriculum that is exclusionary and elitist; that is, Eurocentric, ethnocentric, patriarchal, classist. Such scholarship elucidates the ways in which—along such lines as race, class, gender, sexuality, nationality, ability, and culture—many are marginalized or devalued through this monolithic frame. Some visions and views of human culture, history, achievement, and imagination are privileged over others, it is argued, without acknowledgment of the workings of politics and power relations in the production and perpetuation of what counts as and constitutes curriculum.

Indeed, philosophers have posited humanism as the foundational leitmotif of Western civilization, albeit expressed in diverse ways throughout this history, and in relation to rationalism. Sharing an epistemology rooted in the human struggle to understand and act within the world via the possibilities inherent to the human mind or spirit, humanism and rationalism also lend much importance to education in cultivating these possibilities and such values as freedom, equality, moral responsibility, and social reform.

The inhumanity and violence of modern times have challenged these foundations of Western thought, having shaken this faith in the rational intelligibility of the world and the human capacity via reason to grasp and order it in pursuit of truth and goodness. Though rationalism maintains the primacy of human reason, despite its limitations, certain humanistic objections are made in affirming the value and influence of nonrational human powers and emotions. The critique of rational humanism, though, as a paradigmatic ideology of modernity, is further advanced along these lines through myriad lenses (i.e., [post]structuralism, phenomenology, postcolonialism, ecofeminism) from within and outside the curriculum field—in privileging an unquestioned, normative conception of rationality/reason, and in advancing abstract and individualistic views of human beings that fail to account for constitutive factors like time, context, culture, language, irrationality, and the unconscious.

As scholars have sought to identify differing curriculum orientations, rational humanism can be tied to other formulations, such as Herbert Kliebard's "humanists," which advances ancient cultural legacies, via the disciplines of study. Other similar curriculum orientations included the traditionalist and academic rationalist, and although differences exist among these too. From this scene, rational humanism is affiliated in the United States historically with agents seeking to clarify and systematize school curriculum via emphases on the liberal arts or subject matter study and the development of the student's mental powers and discipline: that is, Charles Eliot and the Committees of Ten and Fifteen reports of the late 1800s, the curriculum revision projects issuing from the 1958 National Education Defense Act, the structures of the discipline interests of the 1960s, and even the standards and accreditation movements from the 1980s into the present day. Complications arise when the use of humanist terminology is sometimes alternatively applied in affiliation with developmentalist, critical, or reconceptualist conceptions of curriculum, or in contrast to rationalistic ones. Some argue that initiatives such as those of Hirsch or as set forth through the standards movement, often identified with the position of rational humanism, are in fact distortions of—even antithetical to—such, reflecting orthodoxy more than rationality.

How advocates of rational humanism respond to these critiques is that even if it has been rooted in Western civilization, it must not necessarily be so, but ought draw globally on all the best of human achievements and riches of cultural wealth, and offer them through the curriculum to all children, and for the sake of human freedom, democracy, equity, and ethics. For rational humanists, cultivating human reason, which includes critically questioning and debating the ways in which it is understood, is still our best hope for moving beyond tribalism and other "isms" at the root of much of the violence and dehumanization present in the world today. The problem is deemed that although many of the ideals of rational humanism have been lauded, little of what it endorses has actually been realized, and is not likely to be so, given contemporary attachments to instrumental and technical conceptions of education, wherein success is defined largely through testing and assessment of only that which can be measured.

Questions central to a rational humanist frame continue to confront curriculum scholars concerning how such things as reason, intelligence, and knowledge are conceptualized, positioned, and addressed via schooling, and the ways in which particular curriculum content is selected, organized, engaged, and legitimated based on assessments of human purpose and worth. Recent developments aimed at encyclopedic and canonical knowledge of the curriculum field itself reflect the swaying power and importance, and heightened via globalization, of this tradition.

## READING

---

Reading is a dynamic and complex process with a curricular history that stretches back more than 1,000 years. The practice of teaching reading has changed across the centuries as cultures moved from primarily oral traditions to written textual communication (1000 CE) to present concerns of a 21st-century technological era. During the last century, the field of reading has been driven by debates about how reading takes place and how best to teach reading in schools. Recent curricular shifts are the result of vast technological changes, the increased role of federal policy in education, and the development of diverse reading theories.

The field of reading has shifted also as a result of a greater inclusion of curricular studies because of the need to broaden theoretical conceptions that encompass language and cultural diversity in teaching and learning. As the changing school demographic in the United States becomes more heterogeneous and linguistically diverse, curricular studies is a natural inclusion in broadening the reading theory lens. The complexity of teaching, studying, and learning to read now requires multiple theoretical models and approaches. As notions of literacy and reading practices continue to expand, curriculum researchers increasingly explore the salience of gender, language, socioeconomic status, family participation, and cultural considerations in shaping reading practices and theories. Reading is a tool of communication in cultures dominated by print and a political and symbolic issue tied to power, social mobility, nationalism, and citizenship. Indeed, curriculum scholars consider the capacity to read a fundamental component of democratic citizenship and human agency.

This entry first presents policy initiatives that have affected reading education and literacy. Next, the theories that have shaped reading curricula, along with current reading approaches and related controversies, are discussed. Then, the assessment of reading curricula is considered. Lastly, the future direction of reading curricula is addressed.

#### Policy Initiatives Affecting Literacy

Governmental policy initiatives have shaped U.S. reading education significantly. For example, federal policy establishing the Federal Housing Authority in the 1950s led to institutionalized racial discrimination in the housing market and affected the property taxes that fund schools. This discrimination led to major inequities in school facilities and materials that affected children's literacy education. Although Title II of the Elementary and Secondary Education Act (ESEA) of 1965 provided funding to elementary school libraries to remedy such inequities, they persist today, even among schools within the same town. Events such as World War II, the Russian launch of *Sputnik* in 1957, and the *A Nation at Risk* report in 1983 increased public perception of a national reading "crisis" and spurred legislative focus on reading

instruction. In 1997, Congress established the National Reading Panel (NRP) to review “scientifically based reading research” and make recommendations for practice and policy. The NRP’s report essentially ignored a large body of rigorous and seminal qualitative research, and at the expense of other vital components of reading instruction, highlighted five key areas: phonemic awareness, phonics, vocabulary, fluency, and comprehension. This report was used to develop the highly influential No Child Left Behind Act of 2001, which touted the goal of every child becoming a reader by Grade 3. Moreover, many states now require schools to provide “English-only” instruction, creating hurdles for English language learners (ELLs) that may diminish and marginalize their native language literacy.

### Theories Shaping Reading Curricula

Various reading theories shape contemporary reading curricula, each positing different ideas concerning the roles of readers and authors in the reading process, the nature and sequence of learning to read, and the role of culture in literacy learning. The *cognitive processing model*, which emerged in the late 1920s, asserts that all meaning resides within the text. In this model, the reader’s job is to understand the author’s message on a literal level, without question, often through memorizing minute details of the text and conducting painstaking literary analysis. In contrast, *sociocognitive approaches* that emerged in the 1940s posit that meaning arises from the interaction between the text and the reader’s background knowledge and experiences. David Rumelhart’s interactive reading theory was the first to suggest that the reader brought background knowledge and personal purpose to the text. The interactive theory later evolved into the transactional reading theory, also known as reader-response theory, with a deeper consideration of the reader’s stance. The transactional theory suggests that each reader experiences a unique reading of a text that is an amalgam of the writer’s intentions and the reader’s experiences, cultural background, subject knowledge, and historical and situational context. The reader is located front and center in the reading process with consideration for differences in language and cultural background.

*Sociocultural theories* of knowledge development, such as the work of Lev Vygotsky, emphasize the role of social forces and culture in language learning, particularly relevant issues for instruction of ELLs. *Critical theory* has also shaped reading education, primarily through the work of Paulo Freire, who advocated for the emancipatory power of “reading the word and the world.” Freire asserted that people should read all texts critically, connecting the messages to their socially situated contexts and making personal decisions about their actions for social change, or *praxis*. *Postcolonial theory* has been used to analyze how governments manipulate formal curriculum and language to colonize the cultures of those they invade. As the Internet has emerged as a primary print medium, *postmodern* and *semiotic approaches* to the reading process emphasize the variety of texts people “read” and the myriad of communicative modes available. Unlike previous centuries in which printed, linguistic text was the dominant site for reading practice, present-day readers must include sign systems such as visual images, art, audio, and moving and hybrid texts in their reading repertoire. Multimodal reading acts, considered *new literacies*, are typically found within Internet social networking sites, student-created digital videos, blogs, and Web pages. These developments have changed the nature of what we define as texts and have spurred changes in what people read, how humans interact with text, and thus, reading curriculum.

### Current Approaches

Current reading approaches encompass what scholars term the four-cueing systems of reading. These language systems assist the reader in processing the text: the grapho-phonemic system (print knowledge), syntactics (grammatical systems of language), semantics (word meanings), and pragmatic systems (knowledge of the situational purposes and functions of language). However, instructional design using the cueing systems differs depending on the teacher’s theoretical lens. For example, if one views reading from a cognitive processing perspective, then one assumes that the reader brings no knowledge to the reading event, and comprehension instruction will likely consist of reading a passage and answering literal-level

questions. But a teacher with a transactional theoretical perspective would acknowledge that the reader brings a mosaic of texts previously read and his or her personal background, such as one's cultural and religious beliefs, to bear on his or her understanding. This teacher might employ literature discussion circles and provide multiple options for reader response, leaving room for individual interpretations of the text. These theoretical developments in reading have also required teacher education programs to consider new approaches to reading curricula, moving from their historically narrow focus on reading instruction to a broader conception of literacy that encompasses language arts/writing and children's literature instruction. However, many reading/literacy programs still address writing and children's literature pedagogy in a cursory manner.

To comply with No Child Left Behind (NCLB) requirements for *scientifically based reading instruction*, many schools use *basal readers*. These readers, which are mass-produced by textbook publishers, are characterized by student anthologies of stories at controlled reading levels and teacher's manuals with explicit lessons for skills instruction. They were popularized in the late 1950s with the Dick and Jane series and have evolved to include more high-quality children's literature from respected authors. Basal readers offer teachers instructional support, provide leveled texts with limited vocabulary for easy reading, facilitate instructional planning, and increase uniformity in instruction. However, publishers may excerpt original literature and alter illustrations, which can damage the integrity and cultural authenticity of the literature. Teachers' overreliance on basals may also lead to a "one size fits all" curriculum with ineffective fill-in-the-blank type assessments and little room for individualized instruction or student-relevant inquiry.

NCLB mandates scientifically based reading research methods that include the five components of reading, whole-group instruction with basal readers, and the use of standardized assessments as measures of progress. Although many have celebrated the spirit of NCLB's far-reaching effort to increase U.S. citizens' reading skills, data reports from 2008 indicate that NCLB measures were not flexible enough to accommodate all learners, especially those of cultural and linguistic difference.

Critics also point out the policy's limitations in using standardized testing as the sole measure of teacher and institutional effectiveness, in its effects of undermining teacher agency and professionalism, in tying monetary and organizational sanctions to student test scores, and in compromising the aesthetic aspects of reading for children.

As an outgrowth of NCLB policy, contemporary educators commonly identify phonics, phonological awareness, fluency, vocabulary and comprehension as essential, interrelated components of instruction. *Phonological awareness*, an auditory process, is the ability to hear and orally manipulate language sounds and is an essential skill for successful reading. When reading instruction starts to incorporate the graphic symbols of letters, helping students understand how the sounds map onto printed letters, phonics instruction has begun. Phonics curricula vary in approach. *Synthetic phonics* methods focus on sequential mastery of letters and sounds and word building with mastered letter-sound combinations. More discovery-based, *analytic approaches* lead students to investigate spelling patterns in words and incorporate tentative spelling knowledge in their writing. All effective reading curricula include explicit phonics instruction, but they differ in the degree to which the phonics instruction is embedded in whole, authentic text or taught through isolated words and skills.

Across instructional approaches, comprehension is the ultimate goal of all reading and should be at the forefront of curricular design. A child's reading fluency and vocabulary knowledge are related to reading comprehension. *Fluency* consists of prosody (smoothness, tone, and expression), the rate or speed of reading, and accuracy. Researchers have discovered that, in the primary grades, assessment of a child's fluency as measured by reading rate can predict early reading success; however, overuse of reading rate as a measure of ability may lead to "word calling" in which students read quickly and accurately but do not comprehend the text.

Although traditional vocabulary instruction involves writing words, their dictionary definitions, and a sentence using the target words, experts currently recommend more varied and contextualized approaches to increase effectiveness. Humans have no upper limit in the number of new words they can learn from reading, but

wide reading must be supplemented with vocabulary instruction that includes clear, child-friendly definitions, rich discussion of new words, exploration of their varied contextual uses, and study of the *morphology* (roots, bases, and affixes) of words. Because a wide variety of texts, volume of reading, and assistance with reading affect a reader's success, these needs put families and schools with fewer resources at a disadvantage that can have long-term effects on their economic opportunities and cultural knowledge. Researchers have investigated ways to lessen the negative effects of poverty on reading development through summer reading programs, family literacy practices, and incorporating children's lived experiences in literacy curricula.

Reading experts and educators have referred to debates about the best approaches to teach reading as the "reading wars." During the late 1980s, a dichotomy arose between whether reading development should be fostered as a *top-down process* emphasizing meaning through whole, authentic reading contexts, or a *bottom-up process* emphasizing systematic and sequential mastery of skills, including phonics, before exploring whole texts. Discontent with this false dichotomy resulted in the development of new philosophies, such as balanced or comprehensive reading, which include both bottom-up and top-down processes. Effective practice acknowledges that readers come to the reading act with different experiences and incorporates the five reading components through instruction with both whole texts and systematic, explicit skills instruction. Classroom teaching takes place in both small, flexible-group and in whole-group arrangements. Early balanced reading instruction often includes read-alouds, shared reading and writing, and expressive language play. Curricular materials may include basal texts, extensive classroom libraries with multicultural children's literature, leveled texts for individualized or small-group instruction, and word walls for phonics and vocabulary development. Teachers may also provide opportunities for *sustained silent reading* (monitored independent reading practice) and highlight the reciprocal nature of reading and writing in "reading workshop" and "writing workshop" curricula.

Technology influences the curriculum and practice of teaching reading in schools today. Though

some argue that new technologies exacerbate issues of access for children from low-income families, recent research indicates that children access the Internet and various technologies at the homes of friends or extended family members and at public libraries. Early literacy computer programs emphasize the grapho-phonetic side of the reading process (i.e., letter and sound identification). Computer-based fluency programs often focus on cognitive processing and rate of reading; some support the reader by suggesting missed words or by providing other prompts. Students can record their own reading and measure their pace to self-assess their fluency or create podcasts of stories they have written to be shared with a wide audience. Additionally, whole books can be downloaded on electronic media for children to listen to at their leisure, and the potential for composing original texts in multimodal ways for a global audience is endless.

### Assessment

Assessment is key to evaluating the effectiveness of reading curricula and instructional strategies, but how best to evaluate what constitutes "progress" and "competency" have been deeply contested issues. Questions arise regarding how to balance the assessment of individuals at varied developmental levels and group progress in classrooms. Educators use a variety of assessment tools, including teacher-directed *formative assessments* that measure a child's progress and help design instruction, teacher or district developed *summative assessments* to evaluate a child's skill acquisition or performance, and outsider-developed *standardized assessments* that seek to measure performance on a standard set of skills in a uniform manner. Standardized assessments often use benchmarks or set developmental goals for mainstream readers—those without cultural or linguistic difference (from middle-class Anglo-Americans). Additionally, technology-based assessments support frequent, large group administration.

Response to Intervention (RtI) is the latest approach that the Individuals with Disabilities Education Act 2004 (IDEA) has mandated to reduce the numbers of children who have reading difficulties and who are referred for special education. Indeed, 80% of learning disability referrals

are for children needing support with reading and language. Most of these readers do not have cognitive impairments but rather need extra, specialized support. In the RtI instructional model, this support takes the form of differentiated instruction with frequent progress monitoring (classroom-based assessments) provided by a collaborative team of teachers including the speech, regular classroom, special education, and English language learning teachers. Ultimately, the goal of effective assessment should be to inform instructional decisions and design, in which case classroom-based, teacher-directed formative and summative assessments provide the most direct, efficient, and individualized data to use in making prompt instructional modifications.

### Future Directions

Reading is a complex and dynamic process central to curriculum studies. Although some scholars have prescribed particular types of reading as imperative to forging knowledgeable citizens and maintaining “cultural literacy,” others have argued that individuals’ solitary experience of reading expands and enriches their humanity. Future comprehensive reading curricula will consider the multifaceted nature of reading for a diverse society. In the end, however, it is not the curriculum materials that make good readers; it is autonomous, knowledgeable teachers within the living curriculum that make the difference.

## READING, HISTORY OF

---

The history of reading curriculum encompasses political and ideological forces as well as research and theory on fundamentals of the reading process. Although adults have used varied techniques to help children interpret symbols and language for thousands of years, U.S. educators did not develop formal, systematic reading curricula until the common schools emerged in the 1820s. The expansion of public education, technological advancements in printing, and the growing importance of print culture in the 19th century increased opportunities to read and advanced reading as a field of study. Despite these advancements, sharp inequities in reading opportunities and access to materials endure today; social prescriptions of who can and should read have been linked to race, socioeconomic class, gender, citizenship, and nationality. Historically, reading curricula have shifted from an eclectic mix of rote memorization, Biblical reading, and “whole word” instruction to systematic, research-based and assessment-driven reading practices. Throughout these changes, the goal of reading curricula has remained the same: to create a literate U.S. citizenry.

Most U.S. citizens had limited access to printed materials or reading tools before the 19th century. In the 1700s, while social elites had financial resources and leisure to access texts, most farming families of rural United States perceived reading, beyond basic facility with contracts and knowledge of religious texts, as utterly wasteful. As a budding “U.S.” identity emerged in the wake of the American Revolution, citizens began to idealize the potential of public education to forge a “civilized” nation and assimilate diverse immigrants into a shared culture. Changing beliefs about the purpose and value of reading, and the emergence of literature written specifically for children, spurred the development of systematic reading curricula. Literacy rates increased steadily throughout the 19th century, albeit with significant differences across race, gender, and class, and

by the 1860s, more than 90% of Northern European Americans were literate.

Technological developments and economic forces were integral in the shift from localized reading curriculum to more systematic and widespread practices. The cost of paper and printing decreased, the efficiency of producing texts increased, newspaper circulation blossomed, and the advertising industry began to promote texts as consumable products. Publishers seized opportunities to market their wares for profit, producing varied texts that facilitated literacy, including textbooks, youth magazines, hymnals, and popular fiction. Whether an advertisement or a Bible, any printed text available became important literacy tools for people of color, immigrants, and women with limited access to schooling.

Approaches to school-based reading instruction varied from holistic teaching of classical literature to segmented skills and grammar exercises. Young children's reading instruction focused on articulation, pronunciation, and elocution, and later instruction included handwriting, oral recitation, reading primers, and reading aloud as a primary way to demonstrate knowledge. During the 1800s, basal readers, such as the popular McGuffey series with its subtle moral dictums, became the norm for reading instruction. The 1840s and 1850s witnessed a major shift in reading pedagogy with Francis Parker's advocacy of the whole-word instructional method in which students memorized sight words before learning letter-sound correspondences. These instructional advances were not available equally; through much of the century, teaching Southern slaves to read remained illegal.

Reading curricula changed in the 20th century in two important ways: More schools became available for poor and minority children, including females, and the advent of IQ testing placed readers in distinct categories for instruction. Scholars began conducting research on reading practices and processes that focused on fluency, eye movement, and short-term memory. In the 1920s, reading readiness, or the early literacy experiences and prerequisite skills that prepare a young child to read, became a focus of education and remained so throughout the century. By 1924, researchers increased attention to ameliorating reading difficulties, developing assessment strategies, and exploring the idiosyncrasies of individual learners.

Educators advocated silent reading over oral reading, worked to increase reading rate and automaticity to enhance comprehension, and began exploring how readers' background knowledge influences meaning construction.

The post-World War II era ushered in interest in reading motivation and increased attention to vast racial differences in educational access and literacy achievement. The civil rights movement of the 1960s spurred policy changes that increased opportunities for African Americans. Subsequently, the Elementary and Secondary Education Act in 1965 provided funding through Title I for supplemental programs to support readers in high-poverty schools. Reading clinics sprang up around the country to research and provide best practices for struggling readers.

In the 1960s and 1970s, the language experience approach became a common instructional method. Teachers created new experiences for students (such as watching a chick hatch), wrote texts with students about those experiences, and used them to teach reading and writing skills. The "back to basics movement" in the 1970s, a phonics-first approach, developed in resistance to previous whole-word methods of instruction and later gave way to a more comprehensive view of reading as a contextual and meaning-based process. In the 1980s and 1990s, new paradigms of emergent literacy and whole language philosophy highlighted the developmental nature of knowledge about how print works for readers and the importance of whole, meaningful contexts for reading and writing, respectively. Educators began to view readers as active constructors of meaning, emphasizing social and cultural influences on literacy development. Educators also began to realize that homogeneous ability-grouped reading instruction led to what is known as the Mathew Effect in which the good readers improved greatly while poor readers fell further behind. This curriculum structure, also called tracking, typically led to poor teaching for minority children and those of low socioeconomic status.

More recently, in the late 20th and early 21st centuries, reading curriculum has been influenced by vast technological changes, federal policy, diverse reading theories, research into the reciprocity of writing and reading, and interest in reading instruction for adolescents. Educators are also

studying effective practices with English language learners. National concerns about global competitiveness and a perceived reading crisis has intensified the federal role in education, in general, and reading curriculum, in particular, with the creation of the National Reading Panel (NRP) report in 2000 and the introduction of No Child Left Behind legislation in 2001. Although contemporary reading requires one to explore multimodal texts, federal legislation has narrowed, instead of widened or deepened, ideas about curriculum and instruction. Many educators hope the 21st century becomes a time of progressive curriculum change that leads to rich, engaging, reading instruction for diverse learners.

Woods Hole conference that yielded Jerome Bruner's *Process of Education* was held in 1959. It was a time of anxiety over our scientific and technological competitiveness. In curriculum studies, the watchwords were "disciplinarity" and "the structure of knowledge." Against this backdrop, Philip Phenix published his comprehensive philosophy of the general curriculum, *Realms of Meaning*, in 1964.

Responding to the new interest in the epistemological foundations of curriculum, Phenix attempted to counter the narrow emphasis on science and instrumental rationality. ("Empirics" was to become only one of six of his realms of meaning.) Indeed, his defense of meaning as an educational aim can be read as a response to the existential predicament of modernity itself, to its skepticism, alienation, and fragmentation. In an era of exploding information and hyperspecialization, Phenix offered a vision of a whole curriculum for the whole person.

In the tradition of Ernst Cassirer's *Philosophy of Symbolic Forms*, Phenix analyzed the myriad subjects and disciplines into six fundamental modes of human meaning making. Moral, aesthetic, and personal ways of knowing thus joined the more familiar logical and empirical modes. In this respect, *Realms of Meaning* could be said to have anticipated the basic argument of Howard Gardner's much celebrated *Frames of Mind* (1983) by some two decades.

For Phenix, meaning has both a subjective side, in the (1) experience of reflective self-consciousness, and an objective side, as it is (2) organized by logical principles into a variety of patterns, (3) elaborated into scholarly disciplines, and (4) expressed in symbolic forms. In Phenix's analysis, these myriad experiences, patterns, disciplines and forms fall into six primary "realms of meaning": (1) symbolics (ordinary language, mathematics, and nondiscursive symbolic forms), (2) empirics (the sciences), (3) aesthetics (the arts), (4) synnoetics (intra- and interpersonal meanings), (5) ethics (moral meanings), and (6) synoptics (comprehensively integrative meanings).

A curriculum organized around these realms of meaning, Phenix argues, would still include the disciplines, but would approach them differently. Disciplines would be presented not as bodies of knowledge already constructed, but as groupings of representative ideas and distinctive methods of

---

## REALMS OF MEANING

---

*Sputnik* was launched in 1957; the National Educational Defense Act was passed in 1958; the

inquiry. For example, in mathematics, students might first learn about sets, elements, functions, and rules of combination; all specific mathematical knowledge learned subsequently can therefore be seen to grow out of these fundamental concepts of knowledge formation. Thus, what is unique about each discipline is presented, but the stress is on the unity of meaning across disciplines. In this way, Phenix suggested, it should be possible to craft a curriculum of general education at once comprehensive and unified.

Phenix suggests that learning should begin in symbolics, followed by empirics and esthetics once language is learned. Ethics and synnoetics should wait until the child is older and has acquired the necessary experience to undertake inquiry in a free, self-directed manner. Finally, study should culminate in synoptics, because this realm encompasses all of the others. The idea is only that the realms be introduced in this order; Phenix acknowledges that strict sequential study is neither possible nor desirable.

Finally, Phenix stressed the importance of imagination in the teaching of meaning, unapologetically placing the importance of wonder before that of practicality. For Phenix, the desire to learn grows first and foremost from a desire to awaken one's own inner life as opposed to satisfying some set of external, social demands.

*Realms of Meaning* is no longer in print, and some of Phenix's specific claims about the disciplines may appear dated. However, when one considers his radical reconstruction of the school curriculum around the fulfillment of meaning, and when one considers that the threats to meaning identified by Phenix have only increased, *Realms of Meaning* might well be ahead of its time and ours.

## RECONCEPTUALIZATION

---

The concept of “reconceptualization” refers to a paradigm shift during the 1970s in the academic field of U.S. curriculum studies. This cataclysmic event occurred after the field's crisis at the end of the 1960s when, it became clear, curriculum development was no longer its primary province. The field was reconceptualized from a largely bureaucratic and procedural field to a theoretically sophisticated field devoted to understanding curriculum. This paradigm shift reflected both changed circumstances external to the field and intellectual developments internal to the field. As a consequence, not only the professional identity of curriculum studies scholars changed, but the research they conducted, the character of the courses they taught, and the very concepts scholars employed to speak about curriculum changed dramatically and in a relatively short period of time.

By the late 1960s, it is clear that the field was in crisis. The Tyler Rationale had reached the end of its intellectual legitimacy, partly for conceptual reasons, and partly for historical ones. Critics of the rationale pointed to its technicism—that is, its emphasis upon procedure to the exclusion of ethics, and so on—and its political naiveté, as if procedure could resolve ideological differences. Historically, the field had been bypassed during the Kennedy administration's national curriculum reform movement of the 1960s. That was a blow not only to the prestige of the traditional field, as it co-opted the primary professional preoccupation of curriculum professors from the time of the field's inception earlier in the century. That blow, coupled with declining student enrollments in curriculum courses, politically ascendant departments of educational administration and educational psychology, the replacement of retiring curriculum generalists with subject matter specialists (such as science educators), and the paradigmatic instability

within the field itself (i.e., dissatisfaction over the Tyler Rationale) combined to send the field into crisis. Internally, the scholarship of James B. Macdonald and Dwayne E. Huebner laid the ground for the reconceptualization.

Historical events prompted the reconceptualization of the field in another way. The worldwide student revolt of the late 1960s, in the United States linked especially to the antiwar and the civil rights movements, reached beyond even those profound issues to challenge conventional ideas of American culture generally. In addition to political and racial dissent, the 1960s gave rise to the so-called counterculture, to notions of cultural revolution, enacted perhaps most seriously in the People's Republic of China under the leadership of Mao Zedong. In the United States, "heightened consciousness"—which included the practice of Eastern religions—reflected a shift in ideological struggle from conventional street politics to the domains of culture. Nearly every academic discipline associated with the social sciences, humanities, and the arts underwent self-critique and profound change. The curriculum field would be no exception.

Before the reconceptualization of the field, the concept of curriculum had been understood as the equivalent to what the school district office required teachers to teach, or what the state education department (or, in Canada, ministries of education) published in scope and sequence guides, or, for nonspecialists, simply the syllabus. After the reconceptualization, the concept of curriculum still conveyed those literal and institutional meanings, but it was by no means limited to them and was understood as not only institutional, but, as well, a highly symbolic concept. Now broadly understood, curriculum is what older generations choose to tell (and what they decide to censor) younger generations. So understood, curriculum is understood as historical, political, racial, gendered, phenomenological, autobiographical, aesthetic, theological, and international. These became the central categories of research and scholarship that emerged in the post-Reconceptualization period (1980–1995).

Such a fundamental shift in the disciplinary structure of curriculum studies did not occur without controversy. There has been, for instance, controversy over the use of the term "reconceptualization."

Here the primary questions became, Was the shift in the field that occurred during the 1970s a "paradigm shift" or merely an extension of earlier scholarship? Certainly it was true that the themes of much 1970s scholarship could be linked to the scholarship of progressive scholars such as John Dewey in the earlier part of the century. So-called humanistic approaches and the initial interest in autobiography could be linked to the child-centered Progressives; others pointed to 19th-century Romanticism as an antecedent. The explosion of Marxist, neo-Marxist, and other political perspectives during the early years of the reconceptualization recalled the earlier interests of George Counts and the social reconstructionists. In their adherence to Marxian categories, however, these differentiated themselves from Counts and other social reconstructionists. What became clear was that while the themes of 1970s scholarship echoed earlier ones, the function of the new scholarship was not to change curriculum practice; it was to understand curriculum as political. Because its function was different—not curriculum development, but understanding curriculum—this 1970s scholarship functioned to reconceptualize the character of the U.S. curriculum field, both conceptually and methodologically.

By the early 1980s, the movement to reconceptualize the curriculum field lost the cohesive bonds that had maintained the coalition during its first years of struggle and enthusiasm. Opposition to the traditional field was no longer powerful enough a force for coalition, as the movement had succeeded in de-legitimizing the ahistorical, atheoretical field of the pre-1970 period. Its success was its demise. The reconceptualization had occurred.

## RECONSTRUCTIONISM

---

Reconstructionism is a group of related curriculum proposals that, although evolving from the social reconstructionist ideas of George Counts, Harold Rugg, and Jessie Newlon, developed a distinct rationale and proposal for advancing education as an agent for social reform. This movement differs from social reconstruction in its promotion of a rationale for a social issues curriculum, its use of psychology and sociology to inform this rationale, and in providing specific curricular and instructional guidelines. The developed proposal for reconstruction education was developed by Theodore Brameld with variants presented in the influential synoptic curriculum text, *Fundamentals of Curriculum Development* by the B. O. Smith, W. O. Stanley, and J. H. Shores, all from the University of Illinois.

Brameld developed his proposal in the 2 decades following World War II. Brameld's philosophy of education sought to effect the transformation of economic, political, and cultural institutions through education. Presenting his philosophy as a social progression from John Dewey's experimentalist philosophy, Brameld incorporated into Dewey's epistemology the insights of utopian thinkers and the contributions made by 20th-century inquiry in the social sciences.

Brameld accepted Dewey's model of deliberative scientific thinking as the means to social progress. The limitation of experiential thought, Brameld contended, was its inability to project social ends for which means can then be designed. Utopian thought, for Brameld, provided these ideal goals and motivated inquiry. Brameld expanded the experientialist understanding of human nature to include the insights of Sigmund Freud, Karl Marx, as well as of sociologists such as David Reisman and W. Lloyd Warner. In his description of contemporary society, Brameld criticized the failure to meet basic human needs,

with social analysis evidencing limited control of essential resources and Dewey's scientific deliberation providing a method for social problem solving to reconstruct the social order.

Key elements of the curriculum theory Brameld developed included (1) an inductive approach to determining social values, (2) the mandate to build consensus on social policy, (3) the use of "defensible partiality" in teaching, and (4) the organizing of the curriculum around social problems or spokes of a "wheel curriculum." The inductive approach for determining social values introduced an "unrational" or subconscious basis for determining social values, a "prehension" of basic human needs. Immediate experience provokes recognition of 12 intrinsic values or "prehesive urges" such as food, shelter, vocation, and recreation.

Gaining consensus on social policy was how Brameld interpreted Dewey's proposal for public democratic deliberation. In education, this meant bringing before students a significant social problem, interpreted as an unmet fundamental need. Using the analogy of a jury trial, social consensus worked through stages, beginning with assembling evidence through social research in a climate of discussion and criticism. When viable hypotheses emerge, they are publicly scrutinized for possible outcomes. A course of action is decided and refinement, analysis, and dialogue continue to evaluate the solution in addressing the social problem.

The teacher is facilitator in this consensual deliberation, but also advocates for solutions he or she believes are most effective. In stating a "defensible partiality," a teacher is welcome to promote social causes and state philosophic convictions but only if she or he is also willing to engage in critical and unrestricted debate. According to Brameld, indoctrination is avoided because the learner is free to accept or reject the explicitly stated convictions of the teacher.

Brameld considered the frame from junior year of high school to the second year of college as the optimal time for implementing a curriculum for reconstruction through a wheel curriculum. The hub of the wheel is group consideration of a social issue, based on the prehensive urges. The spokes are groups of students concentrating on different aspects of the issue, coming together periodically to share research and proposals following Brameld's steps for gaining social consensus.

Brameld's personal commitment to his ideas extended to efforts to develop both a collegiate and a high school course that followed a reconstructionist design while Brameld was a professor at the University of Minnesota. Brameld's influence extended, while a professor at Boston University, to Puerto Rico, Japan, and Korea.

In their influential synoptic curriculum, *Foundations of Curriculum Development*, Smith, Stanley, and Shores arrived at the same value construct as Brameld, citing his list of human needs. Their rationale, however, was the contention that realizing these human needs are accepted goals of a democratic "cultural core," the rules, knowledge, and skills by which a social group conducts itself and envisions its future. The task of curriculum building, they contended, was to consider simultaneously cultural elements and social realities, noting where the cultural core is dissonant from lived social experience. Students consider social problems which evidence the contradictions in the culture core and work to resolve the value conflict, refashioning democracy through direct participation. The social problems core was akin to Brameld's wheel curriculum, although employing a time frame more practical for immediate inclusion in the U.S. secondary school.

Other scholars who contributed to elements of reconstructionist thought include John Childs, with an emphasis on the individual's responsibility to contribute in social problem solving, and Kenneth Benne, who emphasized using a social problem solving method developed from Dewey's social philosophy.

---

## RELIABILITY

---

*Reliability* refers to the consistency and repeatability of a measurement when the testing procedure is repeated on a population of individuals or groups. Knowing the reliability of particular assessments is particularly important for instructors who use standardized measures to assess the curriculum. Curricularists should ask about the reliability of measurement tools that they are expected to use in the classroom or within the school to determine its applicability. The usefulness of this score presupposes that individuals or groups exhibit some degree of stability in their behaviors. However, behaviors among the same person are rarely the same. Scores from an instrument should be stable; a higher degree of stability indicates higher reliability because the results are repeatable. The American Psychological Association has defined reliability as the degree to which observed scores are "free from errors of measurement." The measure of error that results limits the extent to which results are generalizable. Different types of reliability estimates can be calculated through specific methods.

Reliability is merely an estimate rather than an exact calculation; thus, it is not possible to calculate reliability exactly. Reliability estimates rank along a continuum on a scale from zero to one. A reliability estimate of zero indicates that the measure is completely unreliable. A reliability estimate of one indicates that the measure is completely reliable. The reliability estimate represents the proportion of variability of a measure that is related to the true score. For example, a reliability estimate of .7 means that the measure is about 70% true and about 30% random error.

The critical information that should be reported on reliability includes the identification of major sources of errors, the size of those errors and the degree of generalizability of scores across alternate forms, administrations, or relevant dimensions. Variance or standard deviations of measurement errors, in terms of one or more coefficients, or in terms of item response theory-based test information functions should also be reported. Generally, three types of reliability estimates are reported: test-retest, parallel forms, and internal consistency. Test-retest is used to assess the consistency of a

measure when it is administered at different times. Parallel forms, or alternative forms, are used to assess the consistency of tests that are designed in the same way from the same content domain and are administered during independent testing sessions. Internal consistency is used to assess the relationships across items or subsets of items within a test during a single test administration. A widely used reliability estimate is Cronbach's alpha, which provides an index of internal consistency.

Each type of reliability estimate has its own strengths and weaknesses. Those factors need to be considered when designing a study because of their potential impact on the reliability estimates chosen. Test-retest reliability is often used in studies with a pretest and posttest design with no control group. However, one disadvantage of this experimental design is that reliability is not estimated until after the posttest has been conducted. If the reliability is too low, this result will affect the meaningfulness and usability of the scale. Parallel forms are used when a researcher is administering two similar instruments. However, the administration of two similar instruments for more complex or subjective constructs can complicate interpretations. Coefficients based on calculating the relationships between test items and subsets of items are not without limitations. Reliability coefficients are typically useful in comparison tests of measurement procedures. However, these comparisons are not usually straightforward. Although a coefficient may show error because of scorer inconsistencies, it may not reflect variation that is indicative of succession of examinee performance or products. A coefficient may demonstrate the internal consistency of the instrument but may not reflect measurement errors associated with the examinee's motivation, efficiency, or health. Thus, when assessing constructs using multiple measures that result in reliability estimates, testing should be conducted in a short period in which individuals' attributes are likely to remain stable.

Reliability estimates are often used in statistical analyses of quasi-experimental designs. A goal of statistical research is to have measures or observations that are reliable. Results from varied reliability estimates will affect the statistical analyses. In test development, researchers should investigate reliability as fully as is practical. When a measure is not repeatable and consistent, it is not

trustworthy or dependable. Reliability can be improved through a variety of methods. For example, internal consistency in a test can be improved by substituting more reliable for less reliable items. Also, increasing the number of reliable items on the test will increase the total reliability of the scale. Reliability can also be improved by standardizing the data collection process because this will reduce random error. However, although standardization refers to the data collection process, it also applies to the raters, forms, and occasions (times). Training the raters to use systematic procedures can help reduce the errors caused by individual differences and how the raters make judgments while using identical test instructions. The use of similar test environments will also help standardize the process for the use of parallel forms when calculating test-retest reliability.

Establishing reliability does not solely pertain to quantitative research. Although it is not referred to as "reliability" in qualitative research, it can be established through confirmability, triangulation, and extensive time in the field. *Confirmability* refers to having more than one person analyze the data. Triangulation is the process of gathering and corroborating evidence from different individuals, types of data, and methods of data collection in descriptions and themes, whereby the researcher looks at the data from multiple perspectives. Triangulation increases reliability because it ensures the accuracy through multiple sources. For example, a researcher who is interested in studying self-regulated learning in middle school mathematics classrooms may interview teachers and students and may conduct observations in the classroom. In addition, the researcher may collect textbooks or lesson plans. The data from multiple perspectives assists in corroborating or refuting findings within a data set. The use of multiple data sources can help establish reliability and enhance the accuracy of the study. Extensive time in the field is also used to establish reliability. Spending extended time in the field ensures that the researcher acquires repeated opportunities to obtain data and can enhance the consistency among the data.

## RELIGIOUS ORTHODOXY CURRICULUM IDEOLOGY

---

The work of education via schooling largely concerns socializing a generation into the norms, values, traditions, and practices of a society or culture, and curriculum is a central agent in this work. Many have suggested that education, explicitly religious or not, reflects what a people deem to be sacred. Here, too, the curriculum, in addressing what knowledge is of most worth, must be recognized as ever ideologically laden: endorsing and inculcating specific, normative ways of knowing and acting in the world in relation to self and others, however tacitly or overtly. Because of this, strengthened by the existence of conflicting values and aims, ideology is an important and ongoing object of address in the field of curriculum studies. Moreover, nowhere is this address more critical perhaps than where matters of religion are concerned; thus, in Elliot Eisner's analysis of current leading curriculum ideologies, he begins with religious orthodoxy. Issuing from the conviction that education is responsible for initiating children into a faith community and belief system deemed to be true and sanctioned by divine authority, this position compels curriculum scholars to confront questions of ultimate and enduring concern regarding the meaning and purpose of human life and how it ought to be lived, and the role of education in asking and answering such questions. This selection continues, through Eisner's work, with a discussion of religious orthodoxy, considering its central claims and challenges, its historical influences, and its abiding implications for contemporary curriculum concerns.

Religious orthodoxy is one of six curriculum ideologies that Eisner posits direct current thought and practice in the field, including rational humanism, progressivism, critical theory, reconceptualism, and cognitive pluralism. Religious orthodoxy is distinctive in its central belief in the existence of God and understanding of education rooted in "his" authority in directing human affairs, largely through divine commandment as interpreted via a sacred text or texts by a faith community. Education works in the service of attending this divine call upon humans by inculcating the young into such—a particular value system, way of living, embraced as right and true, even as the path to eternal life. Curricular decisions are made with respect to and reflect this higher address; that is, examples of Eisner: the Jewish devotion to the study and interpretation of religious texts; the Jesuit Catholic tradition of activism for social justice via education; and the anthroposophic commitment of the Waldorf schooling to the cultivation of spiritual cognition in the young.

Proponents of religious orthodoxy acknowledge the ideological underpinnings to any conception of knowledge and values inherent in any educational purpose, explicitly endorsing their own as truth and avidly working to realize such truth via educational policy and pedagogical practice. The capacity of religious orthodoxy to enact its philosophy is an enviable strength aspired to by nearly all other curriculum orientations. A position on the rise and of increasing political influence in the United States, advocates also ground their claims in humanistic and democratic commitments—those to which few would object—to religious freedom and pluralism that guarantees them the right to the practice of religion, and to affirm their own cultures, traditions, and values to their children via education.

Here, legal proceedings have been initiated by parents and groups who complain that public schools are unconstitutionally indoctrinating students in what they call the "religion of secular humanism." Constitutive features of schools as philosophical mission, curriculum content, and pedagogical practice have been brought under scrutiny regarding the values and understandings they endorse and exclude. Eisner cites the court case *Smith v. the Board of School Commissioners of Mobile* of 1987, in which evangelically religious parents sought to indict the education system for

discriminating against and compelling students to challenge their family's traditions, excluding culturally relevant material from the curriculum, and inhibiting the free exercise of religion and speech, promoting doctrines in direct conflict with the religious beliefs of its students. Debates and charges related to censorship and the curriculum canon, sex education in schools, and the teaching of evolution in science classes or of issues around gay rights, for example, abound and are ongoing.

Critics of this orientation contest the educative purposes of any approach that rests on certainties, discourages questioning, and seeks to indoctrinate the young into a particular worldview deemed definitively true and exempt from critical interrogation. The dogmatic postures against questioning a religious orthodoxy's core tenets and basic beliefs seem to many to be in opposition to the meaning and process of education itself. Eisner particularly raises the question about how much license is possible in a democracy for groups to isolate themselves—that is, via homeschooling, school choice, voucher system, or privatization advocacy—and inculcate their children in unquestioned doctrines that undermine the principles of democracy and may jeopardize its freedoms should they gain political control. Some scholars have linked the position of religious orthodoxy with the political right, and with “conservative modernization,” what Michael Apple has identified with a larger coalition of forces that has shown increasing political dominance. Eisner also suggests that religious orthodoxy in curriculum may be understood to be of even greater scope if dogmatism of other sorts is included therein, like those views of the ultraleft as well as right who are certain of the singular correctness of their own views.

Beyond historically explicit relationships between curriculum and religion—that is, the “Old Deluder Satan Law” of 1647 requiring the teaching of reading for students to embrace biblical truth in colonial America—religion has exerted and continues to exert a powerful yet oft unrecognized influence in the educational purposes, schooling practices, and curriculum materials that become endorsed, established, and contested in society. David Hamilton has outlined a history of curriculum of absolutist and critical forces oppositionally at work and linked with the demands of religion. He traces the first use of the word *curriculum* in an

educational context to attempts of 16th-century Protestant universities to map out a course of theological study for students to follow—in concert with a biblical conception of life as a course to be run, a race of endurance, eternal life to be gained. Hamilton's work suggests that religious ideas and values issuing from a Judeo-Christian tradition have been foundational to the concept of curriculum itself, in the least in its early constitution as an officiating construct in education and schooling.

Abiding tensions exist between the orthodox and unorthodox in curriculum: the work of socialization and countersocialization, of initiating the young into the status quo, or that which is normative, and engaging them in its criticism and transformation. The field of curriculum studies has an history itself of challenging unquestioned orthodoxies and assumptions through a variety of intellectual traditions. Via postcritical analyses, the dominance of rationalistic, scientific, and secular discourses of education and knowledge have been brought under scrutiny, often through a return to the claims of religious traditions—also in response to a perceived moral crisis in education, and a social movement Philip Wexler has described as a widespread effort toward the “resacralization of culture.” Growing bodies of scholarship have also drawn upon hermeneutics, founded in the religiously committed interpretation of sacred texts; sought to understand curriculum theologically, as in the relationship between liberation theology and critical pedagogy; and elucidated how education is inherently a spiritual if not religious enterprise, including efforts at integrating traditions of East and West, and science and religion. Addressing the challenges of religious orthodoxy in curriculum studies is today seemingly all the more relevant in a context of religious war and violence, wherein politics intersects powerfully with religious belief and tradition on a global scale.

## REPRODUCTION THEORY

---

Reproduction theory was developed by Herbert Gintis in 1972 in his critique of Ivan Illich and was expanded by Gintis and Samuel Bowles in their seminal text *Schooling in Capitalist America* published in 1976. Although reproduction theory (also called correspondence theory) now applies to the social and cultural fields, Bowles and Gintis first approached this theory through the lenses of capitalism and the economy. Their work exerted great impact on the field of curriculum studies and provided curriculum theorists with a foundation from which to critique and analyze schools and cultural reproduction. These ideas also reach further back, pulling from the theories of Karl Marx in *The German Ideology*. In what follows, this entry defines reproduction theory in its earliest form, highlights the important contributions of this theory to the field of education, notes the criticisms of reproduction theory, and discusses how the theory has changed since Bowles and Gintis's seminal text.

As Bowles and Gintis illustrated, reproduction theory provided a foundational model illustrating the direct relationship or correspondence between the ways in which the U.S. hierarchical class system functions and the ways in which U.S. school systems operate. In other words, the school corresponds to the capitalist system and then works to help reproduce the current economic system. Bowles and Gintis viewed schools as microcosms of the capitalist system. Thus, schools are institutions that reproduce hierarchical divisions of labor, meaning that there are a majority of docile, passive, economically disadvantaged workers and a

smaller, elite group with the control of supervisors. Educational institutions act as microcosms of the larger economic system in that they reproduce hierarchical relationships within the walls of the school—including the relationships between administrators and teachers, teachers and students, students and students, and so forth—and schools reproduce unequal relationships outside of their walls by preparing the majority of children from low socioeconomic backgrounds for occupations in the same economic strata as their parents, thus maintaining the hierarchical economic cycle and capitalist system. In addition to maintaining unequal relationships, the school system perpetuates the current class system through its daily practices and procedures such as tracking, sorting, and testing and through the use of overt and covert curricula including both content and pedagogy. The classes a child takes, the content of books and lessons, and access to materials and knowledge, then, differ depending on a child's current economic status and projected economic track.

Although scholars and critics have expanded and transformed Bowles and Gintis's initial definition and development of reproduction and correspondence theory, the theories that emerged in *Schooling in Capitalist America* were significant because they illustrated that U.S. education is linked directly to capitalism and to the economic functions and goals of the nation. Bowles and Gintis highlighted the importance of class, particularly its correspondence with education in terms of reproduction of the current economic system, in a way that theorists before them had failed to do and thus moved educational theory away from former, limited functionalist standpoints. In addition, Bowles and Gintis proved that education is not an impartial or unbiased field. Rather, education is, in part, the result of biases and power struggles. They brought to light the inequalities in capitalism and in education. With their seminal text, then, Bowles and Gintis catalyzed an important and much needed theoretical dialogue about the relationship between economics and education and opened the door for a new generation of theorists, both those who expanded the work of Bowles and Gintis and those who argued against the reproduction and correspondence theory.

With these important theoretical findings in mind, critics have since shown the shortcomings of a

reproduction theory as well. One of the most significant limitations was that reproduction theory initially presented a view of society that was far too simplistic on multiple levels. For one, the theory failed to realize that people have agency, although agency is often limited depending on one's environment or situation. Indeed, as critical theorists and intersectionalists have shown, there are multiple, often simultaneously occurring factors that can affect and limit one's agency, such as race, class, gender, sexuality, religion, age, and so forth. At the same time, though, reproduction theory assumed that people from lower socioeconomic classes had no agency at all and merely accepted and followed dominant ideologies without question. In this sense, then, reproduction theory left no room for change or rebellion against dominant ideologies or dominant class structures. With the working class as passive and completely receptive, there was no room for Antonio Gramsci's working-class rebellion or the fight against hegemony. In addition, the theory failed to note that dominant society is not static, although it presents itself as such, and that dominant groups have to work consistently to maintain control. To adequately represent people and institutions, then, reproduction theory had to examine Gramsci's notion of cultural hegemony and ideology or the development of knowledge. Using the past and the present, proponents of reproduction theory had to look at the ways in which control is developed and maintained, both individually and institutionally, and the ways in which people react. As Judith Butler noted of gender, identities are performative in that people both perform a specific gender and a specific gender is performed on them by society. The same ideas of performativity apply to reproduction theory. People have to examine how society simultaneously produces and consumes ideologies and identities.

Along these same lines, the theory was too simplistic in terms of its narrow view of class. For one, reproduction theory, in its early form, imagined a dual class system with no middle. As we know, however, the class system is complex and layered. Although it is more difficult to move up in the class system, class designations are not set in stone, and these designations are not limited strictly to one's economic value. Indeed, since reproduction theory initially emerged, scholars have realized the

importance of recognizing and examining social, political, cultural, and historical contexts as they relate to class and status. As theorists might note, it is vital to examine class, and some scholars might argue that class is a salient factor in certain situations, but theorists and scholars cannot examine class by itself and have the entire picture. In moving toward cultural production/reproduction as a theoretical basis, scholars and researchers must look at institutional development through what Michael Apple terms a "parallel position" or what feminist theorists might term an intersectional position to discover relationships between class, race, gender, sexuality, and other measures of difference. Also, feminists, postmodernists, and other theorists have since noted the importance of moving the theoretical to the level of the individual, or examining the individual and identity development and engaging in self-reflection. It is important to take into context the ways in which different people view the system and its functions. These scholars have shown how reproduction theory has changed to include the intersections of race, class, gender, and sexuality, but theory has also evolved to illustrate that education is individual as well as institutional, and it is necessary to examine identity and identity development in relation to schools and schooling. As noted previously, a major downfall of reproduction theory, in its earliest form, was its failure to view humans as agents of change. Educational theories have since moved in the direction of examining the individual's relationship to the institutional on multiple levels. This is seen as a necessary step to move beyond theory as elite and bridge the theory-practice gap in an effort to move toward praxis.

This said, the school as an institution has come to be viewed as much more complex than reproduction theory initially indicated. As presented by Bowles and Gintis in 1976, reproduction theory did not view the school as a place for political or social action. Just as with the individual, the school lacked autonomy and was simply a mirror image and a tool of the capitalist system. As noted earlier, however, schools are highly political arenas and are undoubtedly places where change occurs. Scholars and philosophers such as Gramsci have argued, in fact, that education and schooling are the results of conflict between the classes rather than simply tools of the elite used to maintain

control. Since the initial development of reproduction theory, scholars have worked to define and understand the position of schools in maintaining and resisting class, political, and social ideologies, and scholars have expanded to focus on how schools reproduce current economic, social, and political ways of being in both overt and covert ways, such as through the hidden curriculum. With the examination and deconstruction of dominant ideologies along with the examination of the individual and identity development and through inquiry and critical dialogue, educational institutions have the potential to become places where social justice and change can occur.

## RESEGREGATION OF SCHOOLS

---

Resegregation is the reinstatement of segregation after a period of desegregation. Although desegregation spurred the multicultural education movement, which has been critical to interrogating, complicating, and broadening the work in the field of curriculum studies, resegregation brings to bear more critical challenges for the field to consider, not the least of which is its impact on the promise of quality education for all children. More than 30 years after the *Brown v. Board of Education* decision, which mandated school desegregation, educational scholars have noted a disturbing trend toward the resegregation of U.S. schools. Since the late 1980s, the number of Black and Latino students attending schools with a 90% to 100% minority population increased significantly, just as the number of White students attending predominately White schools did. Research also confirms that the schools with predominantly minority populations are typically located in central cities, are underfunded and therefore are also under resourced compared with predominately White schools in suburban districts. The impact of resegregation on the development, implementation, and study of school curriculum has been significant.

In 1954 in *Brown v. Board of Education*, the U.S. Supreme Court overturned the “separate but equal” mandate established in *Plessy v. Ferguson* in 1896, and in a follow-up decision ordered U.S. public schools to desegregate “with all deliberate speed.” As many school districts and public institutions of higher education began to implement desegregation plans, students and scholars began to recognize that access was but one challenge in the struggle for equal educational opportunity. Another challenge dealt with the lack of minority representation in school curricula, which was either altogether absent or projected in a negative light. By the 1960s, many underrepresented groups began to push for more and better representation

in school curricula. Their protests rendered the rise of ethnic studies programs in colleges and universities, which eventually became the basis for the multicultural education movement, which has not only called for more representation of minority groups but has also sought to rethink school curricula in ways that support a pluralistic democracy. Beginning in the 1970s, multicultural education was implemented in school districts and institutions of higher education across the nation. At the same time, many public schools were also implementing desegregation plans, which were far more successful in the South, where residential segregation was less of a problem, than in the North. For nearly three decades following the 1954 decision, the notable achievement gap between White and Black students began closing. According to many researchers, this was a sure sign that equal educational opportunity was being realized.

By the late 1980s, however, scholars began to notice a disturbing trend toward resegregation of U.S. schools, a trend that steadily increased throughout the 1990s in major metropolitan areas across the country. Researchers have noted that one of the key factors driving the resegregation trend has been White flight, which is the tendency of White residents to move out of neighborhoods that have been integrated by minority families for fear of a decrease in property values and school quality. In various communities, the result was the reestablishment of racially segregated urban neighborhoods and consequently racially segregated neighborhood schools, which often face a decrease in necessary funding because of decreases in property value and thus, the property taxes, which are important sources of school funding. Financially strapped school districts in urban communities with high rates of poverty have been shown to have multiple curriculum-related problems, such as high rates of teacher turnover, high rates of teachers teaching in areas for which they are not credentialed, significantly less college preparatory courses, and less resources and updated materials. These also are shown to be the schools where the curriculum tends to be dominated by rote learning materials and strategies in lieu of critical engagement and thinking. Since the late 1980s, U.S. public schools have grown more racially isolated, and for some researchers this correlates with the widening

achievement gap between Black and Latino students and their White counterparts.

Besides funding, the phenomenon of White flight reveals another primary dynamic that adversely affects the development, implementation, and study of school curricula as a whole. The idea that a minority presence is a negative presence whether on property values or school quality reinforces many of the traditionally derogatory images and ideas that cast some minority groups as lazy, uncivilized, and intellectually inferior. The circulation and reinforcement of these ideas result in a number of other problematic dynamics, including low teacher expectations and tracking students in remedial and noncollege prep courses among others. In some instances, tracking has also led to patterns of resegregation that take place within desegregated districts or schools. Magnet schools and programs, for instance, which are usually associated with high academic standards and quality curricula, began emerging in the 1960s as a way to deal with racial segregation. They were placed in many urban districts or particular schools to attract White students into majority minority districts and schools. However, although most of the White students are tracked into the magnet programs, most of the minority students are tracked into the general school curriculum. What results is an isolated White magnet school drawing curricular resources from the already struggling larger minority school or district in which it is located.

Although White flight has been an important contributor to resegregation trends, recent decisions in the U.S. Supreme Court are causing far more concern among educational scholars. In June 2007 with a 5–4 decision, the U.S. Supreme Court struck down the efficacy of two desegregation plans in Louisville and Seattle, noting that no student could be assigned or denied a school assignment based on race, not even for the purposes of integration. Many scholars are convinced that this historic reversal of *Brown v. Board of Education* contention that separate is inherently unequal will only exacerbate the resegregation trend in U.S. schools, therefore continuing the drastically unequal educational curricula offered to majority minority schools.

## RESISTANCE AND CONTESTATION

---

In curriculum studies, *resistance* and *contestation* refer more generally to the cultivation of dissenting positions on what is taught, the perspective from which it is taught, how it is taught, and how learners might be inculcated into challenging or refusing to accept dominant perspectives and ideologies.

In working toward a theory of resistance that informs curriculum studies, Henry Giroux makes the crucial distinction with oppositional behavior that he regards as being located too much in individual acts of contestation and defiance, and as such, miss the larger political sources of causation. The genesis of oppositional behavior is seen as residing in individual pathologies and deficits students bring with them to schools personally or as a result of family background or upbringing. Resistance, on the other hand, takes a much wider and deeper view of the reasons for success and failure in schooling. Particular groups are considered to be differently equipped to respond to the hidden curriculum of schooling.

Giroux points to three ways in which resistance is more complicated than it might appear at first glance. First, subordinate groups are not caught up in schools in a static web of hapless exploitation, which dooms them to inevitable failure. Rather, they often bring rich and diverse experiences that enable them in various ways to creatively subvert the reproductive agenda of schooling. Second, the point has to be acknowledged that power never

operates only in a downward direction—there are always moments and spaces from within which marginalized groups can effectively push back through their creative responses. Third, thinking about resistance in this way and how it might be given expression through curriculum studies, provides a more hopeful and optimistic way of regarding schooling for the most marginalized groups, rather than dwelling only on aspects of pessimism and despair.

As part of his attempt to present a theory of resistance, Giroux proposes the need for clarity of criteria against which the existence of resistance can be properly judged. The major criteria proposed is that resistance should exhibit as its guiding principle the notion of emancipation or the extent to which there is evidence of a refusal to accept forms of domination and submission. Envisaged in this way, resistance displays elements of criticism, challenge, revelation, and exposure of contradiction, along with active plans for personal and social reconstruction.

When applied to schools, and curriculum studies in particular, resistance can also often take on a fuller meaning. It refers to a systematic unwillingness by some young people, especially those from minority or class backgrounds different from that of the middle class institution of schooling, to accept as legitimate the authority structures of schooling. There is an interesting history to this struggle over legitimacy, particularly as it relates to high schools. This genesis goes back at least as far as Willard Waller's classic work, *The Sociology of Teaching*. Waller argued that because of the nature of authoritative relationships built into schools, conflict was inevitable. On the one hand, Waller said, there was the adult culture of which teachers are the bearers or the relay, and on the other hand, there is the much more indigenous culture of youth, students, and young people. The two of these are continually in a state of uneasy tension over the struggle for supremacy. Phillip Cusick's study *Inside High School* sought to cast light on a deeper understanding of how high school students make sense of schooling. He found that students actively define an identity for themselves, and this is often against the formal organizational culture and the identity made for them by the school.

In a similar vein, Paul Willis's seminal study in England entitled *Learning to Labour: How*

*Working Class Kids Get Working Class Jobs* also shows how working-class adolescent culture rests uneasily with the middle class norms underpinning schooling, and rubs somewhat abrasively against that schooling. The norms of what are expected in schools—punctuality, passivity, obedience to rules, deference to hierarchy, application to abstract academic learning—can be potent and continual points of contention, contestation, and friction. This nonacceptance, defiance, or refusal amounts to the assertion of quite a different culture based on norms that value living for the moment, having fun (having a “laff”), and generally forming an identity around things adolescents believe to have relevance and meaning for their lives and that matter to them, such as popular culture.

Robert Everhart’s study of a U.S. junior high school entitled *Reading, Writing and Resistance* is a further example in this same genre of the workings of forces that act to define, legitimate as well as contest, and resist what transpires in high schools. In this case, Everhart labels what the school officially valued as reified knowledge, and it was often of a narrow, instrumental, passive, or inert kind that excluded students and their lives. This was in direct contrast to the kind of knowledge students manufactured from their interpersonal relationships, out of connections with families and communities, and out of a sense of their developing selves, which Everhart labeled re-generatively based knowledge. The latter was seen as something young people did in the making of their own history and that to an extent gave them power and made them powerful people, despite the oppressive structures of schooling. The problem in this for Everhart was that the very processes that gave young people independence and power in shaping their identities also acted to deflect their collective attention away from the institutional structures and regularities that were disempowering them in the first place.

Moving away from forms of contestation no matter how well intentioned but that nevertheless collapse down to forms of individual acts of resistance, it is crucial to conceive of resistance quite differently. We might take our lead here from Doug McAdam, Sidney Tarrow, and Charles Tully who, in *Dynamics of Contention*, coined the term *contentious politics* to describe what really amounts to the form of collective political struggle necessary to challenge and supplant what passes as knowledge,

culture, curriculum, and pedagogical processes in schools. The kind of contention they have in mind, as it relates to curriculum studies, is of a kind that engages wide coalitions of groups and constituents in schools and beyond, around agenda common to all of them. Jean Anyon in her book *Radical Possibilities* says that when resistance is conceived of in this more expansive way, then what is really embarked on is a form of political mobilization that no longer allows resistance to remain hidden away in the private grumblings of schools, classrooms, and educational bureaucracies. Rather, resistance must become more pervasive in the way it brings together diverse constituencies in families, communities, and other social groupings. For curriculum studies, this means that the force for change has to emerge from forms of resistance based in the collective struggles of students, teachers, unions, and other community movements and organizations around what serves the interests of improving the life chances of the most excluded and marginalized students.

## RESISTANCE THEORY

---

Resistance theory draws on an understanding of the complexities of culture to define the relationship

between schools and the dominant society. It gained attention in the educational literature of curriculum studies during the 1980s, largely as an outgrowth of theories of cultural reproduction that preceded it. Resistance theory expanded social analyses of schools as sites where dominant ideas, values, norms, and practices reflective of the social division of labor in capitalist society were transmitted to youth through the curriculum and the organization of learning. Questions about how social class mediated learning and social group formations within schools were of central concern. In resistance theory, schools were considered social sites that structured the experience of both dominant and subordinate groups and that served as contested terrain for marginalized youth to manifest their resistance to prevailing cultural formations. Theorists of resistance sought to understand youth labeled as “marginal” and “deviant” in contextually and historically specific ways, focusing their analyses on the root causes, origins, and meanings that youth attributed to their behavior. Specifically, theories of resistance examined how youth generated meaning of their social location in a society marked by social class divisions and how they formed social practices to both cohere as a group and to challenge external forces of domination. Resistance theory builds on notions of cultural reproduction, but breaks away from the more determinate thesis that considers schools as predictable and impermeable sites that reproduce the social order. For resistance theorists, a critical examination of the link between social structures and human agency is essential.

A thorough understanding of resistance theory requires an analysis of theories of cultural reproduction, especially in regard to the principles of cultural formations. Theorists of cultural reproduction defined culture as the level at which social groups develop distinct patterns of life. The meanings, values, and ideas found in social institutions and customs were considered a reflection of how social groups responded to their life experiences. Here, culture was connected to material existence, and questions about the changing dynamics of family, institutional, and social life within an evolving capitalist society were considered. Importantly, theories of cultural reproduction emphasized the possibility of more than one cultural group existing at any one historical moment,

thus leading to an analysis of various social group formations and their relationship to one another. Key to theories of cultural reproduction was the concept of “dominant” cultural formations and “subcultures.” Subcultures were defined as a response to the dominant culture; a relatively autonomous social space with its own meaning structure, activities, and values. Researchers and theorists interested in gaining a better understanding of marginalized youth in schools and other institutional settings investigated the ways that youth articulated their position within the wider social order. Central to these analyses was an understanding that both dominant cultures and subcultures were necessary for capitalist social systems to reproduce themselves. In other words, cultural reproduction theory emphasized the structural determinants of social life, and the meaning that youth generated about their class positions and gendered and racial identities, in group formations identified as subcultures.

Missing from theories of cultural reproduction, however, was an understanding of how youth conformed to or symbolically contested dominant cultural formations, and how they exercised human agency and experience to mediate their relationships to home, school, and the workplace. Resistance theorists began to investigate youth whose behavior was considered “oppositional” in school settings and examined the underlying factors that characterized “deviance.” Resistance theory stressed the structural causes and personal meanings attributed to oppositional behavior and discussed the moral and political indignation felt by marginalized youth subcultures. The central categories of resistance theory include intentionality, consciousness, the meaning of common sense, and the value of nondiscursive behavior.

Work on resistance focused on the formation of street corner identities and rejected the notion of marginalized youth as docile subjects who reproduced their social position within a society marked by hierarchical class relations. The body was considered a site of struggle whose gesturing allowed youth to negotiate and articulate their existence as social, political, and cultural beings. In resistance theory, domination is considered an open and incomplete social phenomenon, both contested and mediated through youth subcultures. Domination is rejected as a unidirectional process

that communicates norms, values, beliefs, and expectations to the subordinated group; rather, this complex process is subject to change and reinterpretation by those in the subordinate group. The interaction between structure and human agency is considered dialectically, as a mutually constitutive and contested ideological terrain. In this sense, behavior such as clowning and other so-called rituals of resistance were studied as forms of communication that allowed youth to invert dominant social meanings. Clowning and rituals of resistance indexed new forms of student communication and brought attention to the complex forms that culture takes within the cultural reproduction process. Considered an alternative outcome at the level of cultural reproduction, resistance theory confirmed the identity of youth as a subculture to itself, to other “cultures” and to the productive process of capitalist society.

Over time, resistance theory has borrowed from various theoretical and disciplinary traditions, in an attempt to evaluate the potential of youth opposition in schools. Neo-Marxist, neo-Gramscian, feminist, and race/ethnicity studies and postmodern theories have shaped both empirical and theoretical studies of student resistance. This helped bring attention to the dynamics of the hidden curriculum and to the unequal divisions of learning in schools. Importantly, theories of resistance provided a new language for understanding youth who experienced indignation as subordinate subcultures, and it opened the analytical pathways to restore a critical notion of agency in studies of school cultures.

## RESOURCE UNITS

---

Resource units are accumulated and nonprescriptive packages of curriculum materials and information that can enhance a given teaching-learning situation. It was a boon to teaching in larger more integrated units of instruction, rather than in isolated and discrete daily lessons. A teaching or curricular resource unit is a set of lessons on a topic with a unified purpose, set of learning content or activities that elicit learning experiences to facilitate the purpose(s), organizational plans to translate the purposes into practice, and evaluation to determine the success of the plans to meet or revise the designated purposes. Harold Albery and Ralph Tyler each contributed much to the development of the idea of resource units that facilitate instructional units, by collecting or designating sources of information that teachers could use to elaborate the instructional unit or plan through the teaching process. Hilda Taba helped to refine the resource unit, as did Roland Faunce and Nelson Bossing in the 1950s and 1960s.

The resource unit was derived as a response to the development of the core curriculum, elaborated by Albery in the 1940s. Core curriculum was a form of curriculum integration that relied on teacher–pupil cooperative planning. It would be developed around common student interests and concerns, contemporary problems and issues, and at the most sophisticated levels, it would be centered within the conscious development of individuals or learning communities by those individuals or communities themselves. The evolving nature of such a curriculum orientation was partially based on the philosophy of John Dewey and other progressives, such as George Counts, William Kilpatrick, Harold Rugg, L. Thomas Hopkins, and Boyd Bode. Such a philosophy eschewed extensive advance planning, which was characteristic of instructional or teaching units. Therefore, the resource unit was devised to facilitate the evolving nature of teacher–pupil planning.

Preordained patterns and procedures were replaced with provision of a vast array of possibilities (e.g., files of ideas, approaches, media, resource persons, print materials, inventories, illustrative projects) that teachers and learners could consider as a basis for imagining what they could do to learn and grow most effectively. With the advent of computerized storage today, the resource file has immeasurably increased potential. This emphasis on flexibility allowed for variation that responded to different abilities, needs, interests, attitudes, background characteristics, and situational exigencies of students.

The content of most resource units, according to Albery initially and promoted by others over the decades, can be categorized as follows: introduction and orientation; purposes and underlying philosophy; scope of the unit to be facilitate; suggested activities; bibliography and resource lists, including teaching aids; alternatives for evaluation; connections to other units; and diverse uses of the unit. Harold Albery and Elsie Albery provided samples of resource units and emphasized the need for facilities, released time, and professional development to develop and to frequently revise them. The consistency, ease of use, and relevance of the previously mentioned components of resource units serve as criteria for evaluating them. More specifically, Faunce and Bossing indicate that resource units should recognize student needs and interests; offer diverse and specific strategies for involving students in planning, developing, and evaluating their curricular experiences; enable socializing activities; present relevant community resources; embody sound principles of learning; spur professional growth through democratic interaction; stimulate reflective thinking in students as well as in educators; provide for easy and efficient use; reflect a consistent philosophy of education; present many more suggestions than any situation can use; and adapt to the range of student maturity levels.

Recently, curriculum books for teachers and curriculum designers by such authors as John McNeil and by George J. Posner and Alan N. Rudnitsky have built on the legacy of these early authors. Moreover, middle school scholars such as James Beane have developed contemporary perspectives on the core or integrated curriculum that give salient practical recommendations for

contemporary curriculum creation that involves teacher–pupil planning.

## RICOEURIAN THOUGHT

---

Paul Ricoeur (1913–2005), a French philosopher in the phenomenological and hermeneutic traditions, offers insights into research methods for curriculum studies and issues of curriculum and ethics. His work has influenced research method through the development of hermeneutics as affecting the conceptualization and practice of qualitative inquiry and narrative inquiry. His work on self-hood (how we become a self and what are the characteristics of that self), while less taken up in curriculum studies, offers important counterweights to curriculum work that focuses on the cognitive/rationalist aspect of being human rather than on a more complete image of the human being as the basis for curriculum thinking and making.

Ricoeur’s work in method falls into three areas: the potential of hermeneutics, the practice of hermeneutics, and the practice of narrative. Ricoeur confronted the question of whether “meaningful action” (taken from the work of Max Weber, the German sociologist who helped establish the “human sciences” as distinctive from the “natural sciences,” laying out the groundwork for qualitative inquiry). Ricoeur asked if such

action could be treated as a text, the original hermeneutic object of inquiry. He argued that meaningful actions are “documents of human actions” transcending the meaning we ascribe to the action as it is occurring. These actions also reveal the contexts within which the action occurs, thus making the larger world present to us (even when we are not aware of this). Hermeneutics offers the possibility of unearthing such hidden meaning. Ricoeur developed the distinction between the hermeneutics of suspicion and the hermeneutics of the restoration of meaning as different practices for unearthing meaning. He called Karl Marx, Friedrich Nietzsche, and Sigmund Freud the “masters of suspicion” because their work was devoted to tearing away the veils of illusion about how society really works. “Tearing away” bears directly on all the hidden curriculum work. The hermeneutics of the restoration of meaning, on the other hand, offers the counterweight to such analysis, without which the work of interpretation is only half complete. One example of tearing away/restoration is William Reynolds’s book applying Ricoeur’s “hermeneutic arche” (“reading” texts and action naively, reading in systematic detail, and connecting the naive reading and the detail to the world to which it refers, seeing how the action/text orients us to live in a certain way) to curriculum studies scholars. Donald Blumenfeld-Jones enacted a critical hermeneutic reading of three iconic dance curriculum texts using ostensive, personal, and historic meanings that intersect in the text. For narrative inquiry, Ricoeur’s three-volume work *Time and Narrative* set important parameters for narrative thinking. Ricoeur distinguishes between plots of narratives and emplotment. Plots are simply the chronological telling of a story and are not yet narratives. For plots to become narratives, they must become emplotments. Emplotments present the particulars of the story as not one thing after another (a plot) but one thing because of another (emplotment). The narrator will offer the details in an order that builds up understanding of the inner and underlying meanings of the narrative and not be as concerned with pure representation.

Ricoeur developed a philosophical anthropology that began in the weakness of human beings and concluded in the development of the self as an ethical being. Ricoeur’s early work on fallibility

and what we are able to do and what is involuntary can inform curriculum studies through an analysis of schools and curriculum as sites of imperfection rather than sites in which we work to perfect children and society. *The Symbolism of Evil* proposes the origin of contemporary guilt and remorse can be found in archaic notions of defilement through contact with taboo objects and sin as internalized defilement. This work can help inform studies of the hidden curriculum of classroom discipline and all forms of ethics education. Lastly, in the later works, Ricoeur turned explicitly to the ethical self. In *Oneself as Another* Ricoeur offers a synthesis of his hermeneutic, narrative, and ethics, providing an alternative to the cognitivist/intellectualist approaches to ethics and ethics education.

## RUGG, HAROLD

---

Harold Rugg (1886–1960) is one of the most prominent and controversial figures in the history of U.S. education. Rugg was a strongly outspoken central figure in the politically oriented branch of the progressive education movement during the first half of the 20th century. Rugg’s legacy may be seen primarily as that of a pioneering advocate for the public school curriculum as a tool for reconstructing society in a manner that would enhance social justice within the larger U.S. society. During his long career, Rugg made significant contributions in

at least four areas of the curriculum field: (1) in promoting a scientific approach to curriculum development; (2) in advancing the cause of a Deweyan-style progressivism; (3) in remaking the social studies curriculum; and, perhaps most significantly, (4) promoting a brand of social reconstructionism through the public school curriculum.

### Rugg as Educational Psychologist

Rugg's early educational accomplishments were in the field of educational psychology. These were partly the result of his formal training at Dartmouth College as a civil engineer and in teaching engineering at Millikin University. He received a doctoral degree in education from the University of Illinois in 1915 and began teaching at the University of Chicago. During World War I, Rugg worked with Edward L. Thorndike on a project that resulted in the development of the first aptitudes and intelligence tests for adults. Moreover, Rugg's early work in the field of curriculum betrayed his tendencies toward an empirical approach to curriculum development, attempting to scientifically select the content to be included in the social science curriculum.

### Rugg as Deweyan Progressivist

In 1920, Rugg was hired by Teachers College, Columbia University, where he remained on faculty for more than 30 years. Early on at Teachers College, he shifted from his early interest in the possibilities of science for improving education to the second phase of his career, during which he advocated for child-centered forms of progressive education. Rugg's progressivist leanings were also evident in his work as one of the founding members of the John Dewey Society. Moreover, in 1928, Rugg (with Ann Schumaker) wrote a groundbreaking book about progressive education (arguably his most influential) entitled *The Child-Centered School: An Appraisal of the New Education*.

Rugg shared Dewey's belief that the general curriculum should honor the interdependence of the interests of the child, the content of the curriculum, and the surrounding society. Rugg's concerns about an overemphasis on the subject matter in the curriculum resulted in the landmark *26th Yearbook of the National Society for the Study*

*of Education*. Edited by Rugg, Part I of the yearbook provided a lengthy history of curriculum development with emphasis on the importance of the position of the child in the process. Part II, also edited by Rugg, consisted of the proceedings of two yearlong deliberations regarding fundamental curriculum issues. Participants in these deliberations, chaired by Rugg, were most of the outstanding leaders and scholars in the field of education at the time.

### Rugg and the Social Studies

Rugg's progressivist leanings could also be found in his work as a cofounder of the National Council of Social Studies. His interest in the social studies would remain with him the remainder of his career. Rugg is credited with developing the first series of school textbooks in the social studies. They represented a first for any subject matter area. His curriculum materials in that area at the middle (junior high) school level began as a set of booklets that were later combined into an extraordinary popular series of textbooks, editions of which were published for 11 years. This series, *Man and His Changing Society*, established a model of textbook publishing that still presently exists. The books also reflected an attempt to synthesize the various disciplines of the social sciences into the more unified notion of social studies.

### Rugg as Social Reconstructionist

Rugg may be best known as one of the founders of the social reconstructionist branch of the progressive education movement. This movement, born within the social ferment resulting from the Great Depression of the 1930s, sought to enhance the role of the public school curriculum in reconstructing society. These reconstruction efforts were to be aimed toward the redressing of social, economic, and political ills that were seen as threatening the foundations of U.S. democracy.

Three of Rugg's most prominent books contributed greatly to reconstructionist thinking. These were *Culture and Education in America*, *The Great Technology*, and *American Life and the School Curriculum*. These books, along with his other writings, revealed Rugg's continuing beliefs in the contributions of curriculum and the schools

in social engineering. In later years, however, Rugg turned to the role of the imagination and creative self-expression in producing the kind of personal integrity needed by citizens of a genuine democracy. However, some historians have suggested that the major difference between Rugg and other social reconstructionists was the fact that his ideas were disseminated far beyond the pages of his scholarly books. Woven into the texts of his popular and influential textbook series, his ideas were widely available to public schoolchildren. It was apparently this fact—along with his general outspokenness—that provoked vociferous attacks on his work from the American Legion and other politically conservative groups.

## **SAGE HANDBOOK OF CURRICULUM AND INSTRUCTION, THE**

---

*The SAGE Handbook of Curriculum and Instruction* (2008) is 604 pages in length, divided into three parts and six sections. The editor of the handbook, Michael Connelly and the two associate editors, Ming Fang He and JoAnn Phillion, organized the book around practical issues in curriculum studies:

Part 1: Curriculum in Practice

Section A: Making Curriculum

Section B: Managing Curriculum

Part II: Curriculum in Context

Section C: Diversifying Curriculum

Section D: Teaching Curriculum

Section E: Internationalizing Curriculum

Part III: Curriculum in Theory

Section F: Inquiring Into Curriculum

Each part has an introduction, written by Ian Westbury, Allan Luke, and William Schubert, respectively. In all there are 26 chapters. The intent of *The SAGE Handbook* is to create a working vision of curriculum studies that respects its diversity; provide a comprehensive and inclusive set of

authors, ideas, and topics; and incorporate an international, global, and comparative outlook. The book aims to represent the curriculum field without delving into specific subject areas such as math or social studies. Also, to follow-up on Philip Jackson's *Handbook of Research on Curriculum*, *The SAGE Handbook* focuses on post-1992 curriculum policy, practice, and scholarship. Reading this text along with Jackson's earlier volume provides a comprehensive view of curriculum studies. The target audience for the book is curriculum and instruction practitioners as well as graduate students and university researchers.

Four aspects of *The SAGE Handbook* stand out. First, the editors note that the curriculum field may be characterized by its "intellectual energy." Earlier declarations of the curriculum field suggested it was "moribund," as Joseph Schwab indicated in 1969, or "confused" as described by Philip Jackson in his 1992 handbook. "Energetic" provides the reader with a sense that the field of curriculum studies is lively, hopeful, and productive.

Second, the editors of *The SAGE Handbook* asked all of its writers to consider global and national cultural intermingling and its impact on curricula. Some chapters focus on issues of diversity within particular countries. Others focus on international and global issues. Some chapters bring into relief racial issues that cause student disappointment, unresponsive teachers, and disempowering curricula. Other chapters reveal the ways in which curricula are meaningful and teachers who are at the forefront of positive educational change. In general, the tone of the handbook is

forward-looking and hopeful. The handbook ends with a call for comparative curriculum studies to explore cultural resources, social development, and the mutual sharing of ideas and knowledge.

Third, this book is dedicated to practical matters related to schools, communities, and governments. Influenced by the ideas of Joseph Schwab, the editors created a book that addresses issues of practice at theoretical, organizational, and scholarly levels. The editors divide education into several areas: curriculum subject matter (e.g., science, language arts), curriculum topics (e.g., gender, diversity) and preoccupations (e.g., implementation, evaluation), and general curriculum theory. One implication of this approach is that along with university professors and their students, the book is aimed to appeal to policy makers, curriculum developers, and other educational practitioners.

Fourth, in the last chapter, Connelly and Shijing Xu summarize *The SAGE Handbook* by noting that each chapter offers a different window and mapping of the curriculum studies field. Yet, with their Confucian way of examining curriculum studies as a whole, the authors view the field as continuous, made up of various layers of perspectives that form and melt away only to create new perspectives. The authors do not see the curriculum field as discontinuous, filled with starts and stops.

Almost all of the major names associated with curriculum studies can be found in *The SAGE Handbook* as author, as consulting author, or in the author index. Although it would not be fruitful to list all of the chapters and its authors, the naming of a few of the chapters might provide readers with the breadth and character of subjects discussed in this handbook. Here are approximately one-third of the titles with their corresponding authors: "Curriculum Planning: Content, Form, and the Politics of Accountability" by Michael Apple; "Curriculum Implementation and Sustainability" by Michael Fullan; "Curriculum and Cultural Diversity," by Gloria Ladson-Billings and Keffrelyn Brown; "Immigrant Students' Experience of Curriculum," by Ming Fang He, JoAnn Phillion, Elaine Chan, and Shijing Xu; "Cultivating the Image of Teachers as Curriculum Makers," by Cheryl Craig and Vicki Ross; "Community Education in Developing Countries: The Quiet Revolution in Schooling," by Joseph

Farrell; "Curriculum Development in Historical Perspective," by Wesley Null; and "Curriculum Theory Since 1950: Crisis, Reconceptualization, Internationalization," by William Pinar.

## SAT (SCHOLASTIC APTITUDE TEST)

---

The SAT (Scholastic Aptitude Test) is one of the most commonly used standardized college placement tests in the United States. The College Board, developer of the SAT, reports that nearly 2 million students take the test each year. The SAT is typically taken by college aspirants during the junior or senior year of high school. Examinees may register, at cost, to take the SAT Reasoning test and/or one or more of the SAT Subject tests. Most recently revised in 2005, the SAT Reasoning test yields two scores (Critical Reading and Mathematics) that are usually added together to yield a decision score, along with a Writing score. College and university officials use this decision score, along with other student profile data (e.g., high school grade-point averages [GPAs], writing samples, interviews, letters of recommendation) when making admission decisions. Some postsecondary institutions also require or accept SAT Subject test scores. The College Board offers 20 different subject tests in five categories—English, history, mathematics, science, and languages.

SAT Critical Reading, Mathematics, Writing, and Subject tests are each scored on a standardized metric where  $\mu = 500$  and  $\sigma = 100$ ; thus, the

decision score (combined Critical Reading and Mathematics scores) is standardized with a mean of 1,000 and a standard deviation of 200, and scores range from 400 to 1,600. This standardized metric makes scores easy for students and college officials to understand and interpret.

The SAT is administered on established testing dates at hundreds of group-testing sites in the United States and abroad, most of which are located at secondary or postsecondary institutions. The SAT Reasoning test is divided into 10 sections. Sections range in administration time from 10 to 25 minutes for a total testing time of 225 minutes (exclusive of time for examinee check-in, coding of personal information, and other logistical procedures). SAT Subject tests take one hour to complete, and examinees may take up to three subject area tests in a single testing day.

A plethora of research has been conducted on the predictive validity of SAT scores. Studies typically indicate that test preparation activities such as practice testing and coaching tend to increase SAT scores. Low-to-moderate positive correlations have typically been found among SAT scores, high school grade-point averages, and various college success indicators (e.g., GPA, persistence to attainment of degree), with correlations lower for minority than for White students. Males tend to score better on SAT Reasoning, and English-as-first-language students tend to outscore language minority students. SAT Critical Reading and Mathematics scores tend to underpredict success of female students and overpredict success of language minority students. High school GPAs routinely outperform SAT scores in predicting college GPAs; however the advantage of SAT is the added predictive ability (beyond high school GPA) it affords college officials. Although SAT scores moderately predict first year college GPAs, predictive accuracy of college GPA tends to diminish as students move further in their college careers perhaps because of both attrition and differentiation in courses of study and grading policies across majors.

Despite its wide scale popularity, the SAT is not without its critics. Over the last decade, concerns about the length of the SAT Reasoning test, content biases for certain demographic subgroups (particularly minority and poor students), and College Board scoring errors have prompted many institutions to reconsider use of the SAT and other similar

admissions tests resulting in SAT-optional admission policies, and in some cases, elimination of the SAT from consideration in admission decisions.

## SAVAGE INEQUALITIES

---

In the mid-1960s, Jonathan Kozol, a public elementary school teacher, published *Death at an Early Age*, a riveting account of teaching 4th grade in Boston. He documented in detail the banal humiliations, mistreatment, and injustices endured by poor Black students in Northern schools. The book won a national book award and helped to galvanize the movement for full human and civil rights as it moved into the cities of the North. Kozol later marched with Martin Luther King Jr. and became widely recognized as a pivotal figure in the struggle for equity in education. In his book, *Savage Inequalities*, Kozol illustrates the hypocrisy in all claims of equal opportunity and access by comparing schools for the privileged with schools for the marginalized and the disadvantaged.

Kozol recognized that schools serve societies, and that in many ways all schools are microcosms of the societies in which they're embedded—they are both mirror and window onto social reality. If one understands the schools, one can see the whole of society; if one fully grasps the intricacies of society, one will know something true about its schools. Apartheid schools would highlight apartheid reality, and racist schools would indict the society that built and maintained them. In an

authentic democracy, we would expect to find schools defined by equality, cooperation, inclusion, and full participation, places that honor diversity while building unity.

Kozol has issued a steady stream of important books for over four decades now: *Illiterate America*, *Children of the Revolution*, *The Night Is Long and I am Far From Home*, and the runaway best-sellers: *Rachel and Her Children*, *Amazing Grace*, and *Shame of the Nation*, each filled with lyrical description, arresting metaphors, and dialogue that is heartbreaking.

His laser-like examination of the class and racial fault-lines haunting American democracy has served for a long time as a kind of atlas from the classroom to the larger society, and with *Savage Inequalities*, he added a new phrase to the American vocabulary. Throughout this book, Kozol reminds us that while many have implicitly settled for the obscene logic of separate but equal—the new apartheid—the promise of *Brown v. Board of Education* was always a moral promise, an affirmation of the full humanity of the descendants of enslaved people, of all people, and the requirement that everyone in a democracy be granted equal education, equal opportunity, and full respect and dignity—nothing less. The right to a decent education is a fundamental human right.

School has always been and will always be contested space—What should be taught? In what way? Toward what end? By and for whom?—and at bottom the struggle is over the essential questions: Who is to be included in the family of the fully human? What does it mean to construct a meaningful, purposeful, and valuable life in the world, here and now? What demands does freedom make? We live in a time when the assault on disadvantaged communities is particularly harsh and at the same time gallingly obfuscated. Access to adequate resources and decent facilities, to relevant curriculum, to opportunities to reflect on and to think critically about the world is unevenly distributed along predictable lines of class and color.

A curriculum built in opposition to our savage inequalities would rest on three pillars: (1) *Equity*, the principle of fairness, equal access to the most challenging and nourishing educational experiences, the demand that what the most privileged and enlightened are able to provide their children

must be the standard for what is made available to all children. This must also account for equitable outcomes, and somehow for redressing and repairing historical and embedded injustices. (2) *Activism*, the principle of agency, full participation, preparing youngsters to see and understand and, when necessary, to change all that is before them—a move away from passivity, cynicism, and despair. (3) *Social literacy*, the principle of relevance, resisting the flattening effects of materialism and consumerism and the power of the abiding social evils of White supremacy, patriarchy, homophobia, militarism—nourishing awareness of our own identities and our connection with others, reminding us as well of the link between ideas and the concentric circles of context—economic condition, historical flow, political power, and cultural surround—within which our lives are negotiated.

Kozol's message, harsh and unyielding, angry and yet profoundly hopeful, demonstrates that idealism, moral conscience, and outrage might be useful for recovering our voices and our bearings in the long trudge toward freedom.

## SCHOOL CHOICE

---

The topic of school choice refers to programs that offer parents an opportunity to choose the school they believe is best for their children. This is a hotly debated topic in the field of curriculum studies that affects school performance and curriculum goals. Most public school districts assign children to schools in their residential area. Today, many school districts offer families with children in poor-performing schools the option to enroll

their children in other education programs. School choice offers a number of alternatives to public school. There are magnet schools, charter schools, open enrollment programs, specialty schools, vouchers, tax credits, alternative schools, and homeschooling.

What lies behind the current school choice movement is a neoliberal view that favors small government and market control in education. That is, what programs are offered and which schools provide them should be decided by the economic principles of supply and demand, rather than being regulated by government. In this model, education is a product to be sold, school is the supplier, and parents and children are consumers.

This neoliberalist view in education stems from the belief that consumers should have the freedom to choose a product they want, and this exercise of choice drives schools to improve through competition. As business advances and companies compete for consumers, high-quality education comes from schools striving to supply education programs and curriculum that satisfy students and their parents. In fact, proponents of school choice often justify their beliefs with criticisms of government-regulated public schools. They claim that U.S. public schools are often bureaucratic and unresponsive to parents and that they fail to educate children to meet the challenges of the modern industrial world. Labeling public schools as inefficient and unproductive, proponents of school choice point to public education's monopoly as a roadblock to reform, suggesting that, to improve education, schools should provide options to entice students and force other schools to compete for students.

The promise and allure of school choice has gained many supporters. The current education act, No Child Left Behind (NCLB), adopts choice as one of its major school reform strategies. School choice is steadily spreading across the country. At the same time, school choice has invited unusual opposition and debate among educators. Opponents suggest that study results on the effects of school choice on students' academic achievement have been mixed, and that it is hard to conclude that school choice ensures the academic advantage it promises. Further, they argue that school choice tends to marginalize education for the poor while draining high-performing students from community-based public schools.

A provision of the NCLB Act provides vouchers and school choice to families in failing schools. In some schools, entire populations have moved to alternative schools while local schools are reconstituted or converted to a charter school programs. What these practices have revealed so far is that school choice program results in further marginalization of socioeconomically disadvantaged students. This contradicts the argument that choice gives poorer families equality in access to quality education among students. Another problem poor families face is that vouchers issued to parents that choose to opt out of public schools and move to private schools find that the voucher covers only a portion of the cost of tuition. Further complications arise with issues of transportation, meals, uniforms, and books. Economics often provide poor families few options to send their children to private and parochial schools.

When parents are able to get their child into an alternative program, they find that schools are not obligated to take in or retain any child, and many schools have admittance requirements as a way of controlling their learning environment. With selective acceptance, those most in need of authentic curriculum experiences and additional support may be the ones least favored by schools. Although choice may be feasible for some parents, familiar with the system and financially able, it is more difficult for socioeconomically marginalized families. Often, the local school dubbed as failing is the only viable option for children of the disadvantaged. For these families, vouchers and other choice programs mean financial hardships and a decreased chance at reaching their educational goals.

Another problem educators point out in relation to school choice is the limiting effect it has on curriculum programs and students at under-achieving schools. Under the NCLB act, scores on standardized tests are used as the tool for assessing school performance. Schools that meet the standards are labeled successful, but those that do not are designated as failures. This circumstance tends to lead schools to focus on raising test scores rather than on learning. Teachers drilling information and using instruction time for test preparation, and testing strategies replace exploration and learning experiences in the classroom. Such practices are more frequently present at low

performing schools that are most affected by choice and its consequences.

School choice tends to leave families without any options but public schools to face shrinking support for their children's school systems. This leaves many schools in inner-city poor areas underfunded and unengaged in learning. Thus, some critics suggest that a true educational reform has to begin with curriculum improvement rather than turning to market forces, privatization, and competition to bring about effective learning.

The difficulty of trying to provide the customized education in a competitive learning environment continues to confound school policy makers and planners. The promise of school choice may be possible, but it must meet the needs of the general population while offering support for students with special needs.

## SCHOOLING IN CAPITALIST AMERICA

---

In 1968, in the midst of national upheaval over social equity and educational authority, Samuel Bowles and Herbert Gintis began work on what would later become *Schooling in Capitalist America: Educational Reform and the Contradictions of Economic Life*. Economists and social theorists, Bowles and Gintis set out to understand the growing body of contradictory evidence regarding the efficacy of educational reform. By

the time they completed their landmark work, they had become convinced that there was a much deeper contradiction in U.S. society: that between our egalitarian goal of democratic participation in schooling and the inequalities implied by the continued profitability of capitalist production. Challenging the liberal faith in the school as the great agent of equalization, Bowles and Gintis argued that the hidden curriculum of schooling was precisely the reproduction of inequality. Their analysis of the correspondence between curricular variation and social stratification alone constitutes a major contribution in the history of curriculum studies.

Contrary to a primary assumption of liberal reform, Bowles and Gintis argued that democratizing schools alone would not democratize society. To bring about any genuine change in the order of schools would require an accompanying change in the social relations and economic order of society at large. This is because schools not only impart knowledge and skills (the official curriculum) but at the same time acculturate students into the existing capitalist social order (the hidden curriculum). Schools prepare students for unequal social roles by developing their consciousness and capacities into more or less the forms expected by future employers.

For Bowles and Gintis, variation in school curricula correspond to stratification of social roles: Some schooling emphasizes rule-following and discourages creativity as would befit low-level jobs; some promotes dependability and moderate autonomy as befits mid-level jobs; and a small portion of higher education mirrors the need for high-level professionals to internalize the aims of an enterprise in a deep way. For this reason, Bowles and Gintis proposed that only in a socialist democracy could schools truly develop the full human capacities of all children, in preparation for a future in which students would take their place in a society of equals.

Retracing the history of U.S. schooling from the early 19th century through the present day, Bowles and Gintis demonstrated the incompatibility between the democratic mission of schools and the specific demands of capitalism. For example, they showed how even as workers were able to win more schooling, most of the curriculum was kept out of their reach, and how higher education, once

a luxury for the few, became more accessible precisely as capitalist industry required more knowledge workers.

Bowles and Gintis also critiqued the liberal assumption that economic success in the United States is based on cognitive ability. To the contrary, they cited evidence demonstrating that economic success bears little relationship to conventional measures of cognitive ability such as IQ. Rather, the transmission of socioeconomic status from one generation to the next operates by noncognitive mechanisms.

*Schooling in Capitalist America* also addressed existing educational alternatives such as free schools, in which Bowles and Gintis found more of the same debilitating assumptions about the role of schools in economic life. The socialist alternative envisioned by these scholars imagines neither a coup nor a revolution led by an elite vanguard. In their vision, educational reform must be part of a broad popular movement to transform social relations of production outside and inside schools.

Revisiting their work in 2002, Bowles and Gintis reaffirmed their findings about the inefficacy of liberal reform and the contradictions between U.S. schooling and economic life. In their view, the greatest shortcoming of their book was the lack of a clearly stated program for how socialist democratic schools could better achieve the aims of full human development in a socially equitable world. Nonetheless the analysis and findings of this text continue to reverberate through contemporary educational research, and *Schooling in Capitalist America* remains a classic in the sociology of curriculum, speaking to all those interested in how school curricula could become more genuinely democratic.

## SCHOOL PRAYER IN THE CURRICULUM: CASE LAW

---

Case law regarding school prayer provides direction for understanding the constitutional boundaries of both staff- and student-initiated religious speech. Under most circumstances, prayer as part of the school curriculum is illegal. Several legal challenges to prayer in schools have helped define the role of prayer in public school curricular and extracurricular settings. School officials may allow private prayer by providing a moment of silence as a structured feature of the school day. Moments of silence provisions, however, have met with mixed success when challenged in court. As the study of curriculum history shows, the evolution of public schooling from teaching religious-based literacy to a comprehensive curriculum was challenged in classrooms and courthouses. The role of prayer in the curriculum continues to be a source of contention.

The idea of separation of church and state guides school prayer case law. The Establishment Clause of the First Amendment reads, “Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof . . .” A three-part test established in *Lemon v. Kurtzman* (1971) was used by the courts in deciding school-based Establishment Clause cases for a quarter century, although its influence is considerably weaker under the current Supreme Court. The Lemon Test asks three questions. First, does the state’s action have a secular purpose? Second, is the primary effect of the state’s action either to advance or inhibit religion? Finally, does the state’s action create an excessive entanglement between religion and government? To pass the Lemon Test, the state must show that it can answer yes to the secular purpose question and no to the primary effect and entanglement questions.

Religious speech and study may be part of the public school curriculum if it has a secular purpose and does not have the intent or effect of inculcating religious belief or practice. Lessons on comparative religion, religious imagery in art, or biblical symbolism in literature are common examples of how religion may be introduced in the formal curriculum while still passing the Lemon Test. Even the use of Christian hymns in school choir has been upheld because they historically represent such an important element of choir music. However, case law shows that the courts have consistently ruled against school-sponsored prayer in the curriculum.

Prayer at graduation and extracurricular events is, like prayer introduced during the traditional school day, unconstitutional. In *Lee v. Weisman* (1992), the U.S. Supreme Court ruled that although both attending the graduation ceremony and standing to pray at the ceremony were voluntary, there is injury to students who feel compelled to make the choice to abstain from the prayer or not attend their graduation. Social conventions, the Court argued, must be considered when considering the practical implications of not participating in state-sponsored prayer. The opinion of the Court affirms, "The Constitution forbids the State to exact religious conformity from a student as the price of attending her own high school graduation." Moreover, the environment of the graduation ceremony is "directly analogous to the classroom setting" when considering the risk of compulsion.

Student-initiated prayer at graduation is also a violation of the separation of church and state. In *Lassonde v. Pleasanton* (2003), the Court ruled that school officials are within their rights to limit free speech of students when necessary to uphold the Establishment Clause. The *Lassonde* case turned on two central points. First, the school controlled the forum and was therefore compelled to monitor the nature of the speech. Second, the Court rejected the argument that there should be a lower standard for prohibiting sectarian speech because graduation ceremonies are voluntary. Attendance at graduation, for example, is not required to receive a diploma if all other graduation requirements have been met. The Court's view on the optional nature of graduation was that the ceremony itself was a significant rite of passage in the lives of teenagers and no student should have to forgo that privilege in exchange for avoiding

state-sponsored promotion of religion. Only in those cases where it can be clearly shown that the person speaking was acting as a private person, rather than an agent of the school, is prayer or religious speech allowed.

Extracurricular activities, particularly sporting events, have been fertile battlegrounds for prayer in school cases. This is largely because of the popular practice of prayer or invocation preceding school sports, particularly football games in the South. The prefootball game-prayer is also an interesting legal issue because it pushes the boundaries of the definitions of the school-controlled forum and the voluntary nature of both attendance and participation. The issue of school prayer was addressed by the Supreme Court in *Santa Fe Independent School District v. Doe* (2000). In the *Santa Fe* case, a school policy created a mechanism by which a student would be named by a majority vote of the student body to deliver an invocation before every home football game. The Court ruled that although the pregame prayer was student-led and student-initiated, it remained an extension of school policy, under school supervision, and on school property. Regardless of the voluntary nature of attendance, "a pregame prayer has the improper effect of coercing those present to participate in an act of religious worship."

A moment of silence that provides an opportunity for quiet meditation and serves the purpose of creating a venue for individual students to pray is allowable if the policy does not have the primary effect of endorsing religion. In Alabama's *Wallace v. Jaffree* (1985) case, the state changed a policy endorsing a meditative moment of silence for one that explicitly promoted the use of that silent time for student prayer. Although the original legislation was allowed, the amended legislation violated the Establishment Clause because the only substantive change in the law was to promote prayer.

## SCHWAB, JOSEPH

---

Joseph Schwab's major contribution to curriculum studies is the concept of "the Practical," a unique orientation based on educational commonplaces coordinated by traditional problem-solving methods that use arts of the eclectic for modifying and coordinating competing theories to formulate and teach curriculum. From 1969 until 1988, Schwab wrote six articles, beginning with his scathing attack in Practical 1 on the ineffectual state of the curriculum field because of overreliance on limiting theories, often drawn from statistically based social sciences models. The cogency and energy of his presentations opened the curricular field to a greater range of research focusing on issues of praxis, teacher narratives, teacher scholarship, and cultural concerns.

Schwab's Practical articles were the culmination of a career that affected many important curricular innovations of the 20th century—including general education programs at the University of Chicago in the 1940s, the "disciplines" movement and Biological Sciences Curriculum Study (BSCS) in the 1950s, religious curricula at the Jewish Theological Seminary of America (JTSA) in the 1960s, and the foundation of the Institute of Research on Teaching (IRT) at Michigan State University in the 1970s.

### Curriculum Innovation

At the University of Chicago, Schwab graduated with an English major, and went on to a PhD in Zoology (genetics). As chairperson of Chicago's Natural science sequence, he developed discussion methods in place of lectures, introduced primary sources in place of textbook accounts of scientific discoveries, and worked to integrate the sciences with the humanities. In the Examiner's Office under Ralph Tyler, he worked to separate testing from teaching so that the learning bond with the teacher would not be compromised by competition for grades.

As a faculty colleague, dissertation advisor, and classroom teacher, he challenged interlocutors to think through real problems on the spot, without slipping into sloppy anecdotes or vague generalities. He taught nearly every course in the special undergraduate program designed by Robert Hutchins at the University of Chicago and was twice winner of the outstanding teacher award. Exploiting the freedom to explore a variety of subjects and their connections, he developed an impressive scholarship to support his teaching. He represented this in extended essays, such as "What Do Scientists Do," for which he read more than 4,000 books and articles. In both activities, Schwab insisted on dynamic incarnations of ideas because any plausible solution must show the need to know more and know it from more than one perspective.

In 1952 when the University of Chicago program conceived by Hutchins was beginning to alter its curriculum and organizational structure, Schwab shifted his pluralistic view of subject matters to the structures of scientific disciplines. These he examined as modes of inquiry rather than rhetorics of conclusions because most scientific conclusions and methods were obsolete within a few decades. He focused this attention in a series of articles and, as chairperson of the BSCS Committee on Teacher Preparation, edited three widely used versions of its teachers' handbooks.

### The Practical

At the same time as he began work on The Practical, Schwab produced a quasi-practical version of it in *College Curriculum and Student Protest*. This focused his intellectual and character-building orientations on the problems of campus unrest. Using a medical model, he diagnosed the students' turmoil as symptomatic of failings in their schooling, and his prescriptions were curricular changes and innovative teaching methods. The proposals involved eclectic modifications of academic structures and nontraditional uses of traditional liberal arts that would enable students cogently to explore their concerns—a curriculum to improve student protest. He later elaborated the philosophical foundations for these recommendations in extended essays on polity such as "Freedom and Liberal Education."

The six Practical papers (Practicals Five and Six are not yet published) provide a conceptual summary of Schwab's experience in curriculum. As teacher and scholar, he had pulled together such wide experience that he had become a genuine polymath in education. This is evident in his mastery of principals and methods or the five bodies of disciplines necessary to curriculum deliberation, which he called the commonplaces of education, commonplace because their use or neglect always affects curricular planning and execution. The five commonplaces are learner, subject matter, teacher, (social/cultural) milieu, and curriculum making. In any curriculum group, each person needs an experienced representative to compensate for his or her weakness in relation to the expertise of the others. Curriculum making requires a specialist who brings experience as well as wisdom to the deliberation. This specialist must work with the other representatives to ensure proper coordination of the commonplaces because changes in one have consequence for the others. Domination by a single commonplace leads to a theory-based curricula with parochial concerns such as child development, teacher needs, subject matter innovation, or social change.

Each commonplace also has its own commonplaces. For instance, consideration of literary subject matter involves consideration of theories concerning the author, the audience, and the world of the work, as well as the work itself. Consider, for instance, how the collective scholarship that the group brings to a problematic curricular situation—such as reading problems in a precollege remedial program—enables it to formulate the problems in different ways. The reading specialist can provide stimulating books with suitably challenging vocabulary. The milieu expert can tackle such social factors as the dysfunctional model of semiliterate parents. The teacher expert can consider the need to start from a potentially successful base of readings provided by the reading specialist, rather than a standardized one. At the student commonplace, discussion can center on how such media distractions as television can be exploited by using scripts of programs that interest the students.

Schwab envisions another set—arts of the eclectic—to join theories where only one is inadequate for grasping the full import of the problem. The group considers which combinations could be

most effective. As they discover and develop their capacities in the fluidity of discussion, the members particularize the commonplaces in an incremental, local, and ongoing process. The problematic situation evolves into a situation of problems that develop in a spiral rather than a serial progression of connecting and testing problems with solutions.

The Practical is a formidable vision for education that integrates its various realities and activities from Schwab's 60-year engagement with them. Discovery of the commonplaces, development of the arts of problemation, and invention of arts of the eclectic to bridge the theory-practice divide present a unique set of tools for curriculum making. Schwab's vision is set forth in prose that is compact, knowledgeable, and passionate. However, although much quoted in accounts of praxis, it has yet to be fully realized in actual settings.

Schwab pointed out how practical exigencies are endemic to schooling and that those who are closest to the problems, not remote curriculum czars, can become the best problem solvers, given adequate resources. However, when *The Practical* is used, it appears piecemeal, as in the research of Schwab students on various aspects of teacher knowledge and narrative. The need for complex collaborations across disciplinary lines to reform existing school systems helps account for the lack of holistic realizations.

An unsettled aspect of Schwab work is the considerable amount of unpublished material in papers and recordings. The contrast between live deliberations and the more schematic ones in the Practical articles is instructive, especially where he dramatically throws away his curricular script to confront a pressing learning difficulty.

Schwab's Socratic challenge to educators is for questions rather than answers, for use—rather than discipleship—of predecessors like Aristotle and Dewey, and for the widest possible base for education, which is a way for living in a democracy as set forth in the long essay, appropriately named "On Community."

## SCIENCE EDUCATION CURRICULUM

---

Science education is concerned with the discipline of science, as well as with how science is taught and how it is learned, and includes the aims, the policies, programs, and practices that support teachers in their efforts to teach and students as they endeavor to learn science. Since the 1990s, science education is often called science, technology, engineering, and mathematics education or STEM education. Science or STEM education is an important curriculum study because of its connection to the general education of citizens and because of its contribution to an understanding of the natural world.

An understanding of science/STEM education is based on knowing about its aims, about the efforts by national and local governments to develop policies supporting science education, and about the programs and practices implemented by national and local governments, universities, professional organizations, districts, schools, and teachers to ensure that science/STEM education is implemented effectively.

### Aim of Science/STEM Education: Science Literacy

Science literacy is the outcome of science education and has two dimensions. The first is the general

education necessary for a fully realized life. Science literacy also reflects a deep and rich understanding of the natural world as revealed through science, technology, engineering, and mathematics. Scientific literacy enables one to examine experience reflectively, draw conclusions and to make judgments about the dilemmas, enigmas, and problems posed to the individual, the community, the nation, and the world by nature, including health of individuals, populations, and the natural world itself.

Perhaps the most important policy influence on STEM education as it touches on students and teachers has been the conceptualization and then the legislative mandates for the implementation of academic standards, both for science and the other “core” subjects, English language arts, mathematics, and social studies.

The publication of *A Nation at Risk* in 1983 attributed the weakness of the U.S. educational system to its failure to identify in a clear and compelling way the specific objectives for student learning. The remedy was to be the development of clear and measurable statements of what all children should know and be able to do in both the core content areas as well as in the visual and performing arts, health, and physical education.

The science education community responded to the standards movement positively. The American Association for the Advancement of Science, the world’s largest general science society, initiated Project 2061 in 1985. The explicit aim of the founders of Project 2061 was to make it possible for all U.S. citizens to achieve science literacy. Project 2061 initiated collaboration with scientists, educators, universities, and school districts that resulted in a series of documents that culminated in the publication of the *National Research Council of the National Science Education Standards* in 1996. Other documents included *Science for All Americans* published in 1989, *Benchmarks for Science Literacy* published in 1993, and the *Atlas for Science Literacy* published in 2001 and revised in 2008.

When states began to create accountability systems during the decade of the 1990s, the National Science Education Standards were used as the model for the development of individual state standards. The state standards then became the basis for the development of the state accountability

tests. By 2008, all but one state (Iowa) had academic standards along with an accountability testing system.

### **Programs and Practices Supporting STEM Education**

The National Science Education Standards set forth a vision of STEM education consistent with the philosophical foundations laid by John Dewey and progressive educators. STEM education should be parallel with the practice of science as inquiry. Inquiry begins with observation. Reflection on the observation reveals inconsistencies and discrepancies that result in the development of questions to guide the inquiry, the questions lead to speculations that are focused by what is already known. The focused speculations are tested using various strategies to design experiments. The experiments yield results that feed back to the initial observations. The inquiry cycle is often termed “the learning cycle” in the STEM education curriculum materials.

The Lawrence Hall of Science at the University of California at Berkeley was a pioneer institution in the development of curriculum materials that support the inquiry focused standards-based science education. The Full Option Science System (FOSS) kits provide teachers with both the materials and the story line with which to engage their students in STEM education. These materials were developed as research projects funded by the National Science Foundation. They are now commercial products that compete with more traditional textbook-based programs. The influence of these “exemplary” programs is shown by the presence of science and mathematics kit materials that are now a part of nearly all commercial curriculum materials.

### **Challenges to STEM Education**

The implementation of science as envisioned by the science education community since Dewey’s time poses many challenges to states, districts, schools, and teachers. The theory behind the standards movement was simple. If teachers have a clear understanding of what students are to know and be able to do and if the teachers and their schools were held accountable, the teachers would be able to create classroom experiences that would

result in student outcomes that fit the expectation. Unfortunately, the reality has not fulfilled the predictions of the theory.

In the international comparisons such as the Third International Mathematics and Science Study and its successor comparison studies, the International Mathematics and Science Study have shown that U.S. students lag behind “competitor” nations in their understanding of both mathematics and science. On the National Assessment of Educational Progress, the measured achievement of U.S. students has remained flat and the gaps in achievement between White and children of color have been persistent.

The response to this challenge has been to develop strategies to provide professional development for inservice teachers that is more consistent with the tenets of science education. Where teachers in traditional schools work in isolation, professional organizations such as the National Staff Development Council (NSDC) have advocated for professional development beyond the traditional after-school or summer workshop. The NSDC has become an exponent of the development of professional learning communities in schools. These “communities of practice” apply the principles of inquiry learning to the teachers in a school except that the content is teaching and learning in the school’s classrooms.

### *The Standards Challenge*

The development of state standards in the content areas has ironically created an unforeseen difficulty for teachers. Because the standards development process has ensured that the content of the standards in question is accurate and consistent, the standards documents for each of the content areas are large and often overly difficult for teachers to translate into effective instruction. Elementary teachers who generally are responsible for the four core areas may be overwhelmed by the number of standards that their students must master in a 180-day school year.

### *The Testing Challenge*

The passage of the No Child Left Behind Act of 2001 was a mixed blessing for science education in that the law required annual testing of English and

mathematics, but science was to be tested at two grades in Grades K–8 and once in high school. The science education community is concerned that because science is not tested at every grade, teachers at the grades where there is no test will neglect science instruction.

Another challenge posed by both federal and state accountability testing has been the tendency of teachers, especially in schools that are under scrutiny for persistent low performance, to attempt to substitute testing for teaching. Schools purchase “test preparation” materials and use valuable instructional time to use these practice materials.

### *The Evolution Challenge*

Right at the heart of science lies the understanding that truth means something quite different than what it means in most religions. In biology, the centrality of evolution has been viewed as a threat by some religious groups. In Kansas, Ohio, and South Carolina, various groups have challenged both the science standards and the work of individual teachers by demanding, for example, “equal time” to the teaching of content that reflects a more “Bible friendly” perspective or that language be incorporated that is “friendly” to those who do not accept evolution. Although the Supreme Court distinguished between religion and science in the *Epperson v. Arkansas* 1968 case, new challenges claiming not to be based on religious beliefs have emerged. In particular, “Intelligent Design,” the idea that the natural world is “irreducibly complex” and therefore could not have been produced by the processes of evolution has become a new way to raise the old challenge about science education. The courts have generally been supportive of the science education perspective, as in the *Dover v. Kitzmiller* lawsuit.

Whatever happens in courts, teachers know that polling data show that as many as 60% of all U.S. citizens either believe in a literal interpretation of the Bible or have ascribed to the notion that children should be taught both sides of the controversy so they can make up their own minds. Such knowledge has a dampening effect on the teaching of biology in many communities.

Contemporary science education is part of a rich tradition extending back to the work of the progressive educators at the beginnings of the

20th century. An alliance of university professors, high school teachers, professional associations, businesses, and industries have continued to work from two central ideas. The first is that all children should have a deep understanding of how the natural world is investigated and that this deep understanding is necessary for a full and rich life whatever one’s career. Second, the United States needs well-prepared students to study the sciences and to become teachers of science.

## SCIENCE EDUCATION CURRICULUM, HISTORY OF

---

Science education curriculum includes textbooks, instructional materials, and complete instructional programs designed to help students master the content and processes of science. Learning science requires that students acquire a rich understanding of both the science facts about the natural world as well as how science explains these phenomena. Such rich learning requires an equally rich set of instructional experiences. The history of science education curriculum has been defined by the tension between what is known to be good instructional practice and the difficulties that arise when attempting to implement such practices widely in U.S. schools.

When the study of science was recognized as a legitimate school subject during the last half of the 19th century, science education curriculum reflected the current understandings of how children learned; that is, by reading (or being read to) and by recitation of the facts. At the secondary level, students were to study chemistry, physics, and astronomy with a strong laboratory component. However, contemporary evidence suggests that most students were taught science by reading textbooks and reciting what they had read.

The last quarter of the 19th century saw the development of new psychological insights into learning that should be applied to schooling. The most widely cited formulation of the relationship between the mind and learning science is that of John Dewey. In Dewey's formulation, human evolution selected for adaptive intelligence; that is, humans have the ability to learn from experience. Central to Dewey's formulation of that learning as a natural human capacity is the understanding that learning is the result of active investigation of experience.

During the last decades of the 19th and early decades of the 20th century, much thought went in to the development of science curriculum that reflected the psychological foundations of student learning. Work at Francis Parker's Cook County Normal School, at the Laboratory School at the University of Chicago (under the direction of John Dewey), and the development of "project method," as promoted by the Teachers College professor

William Heard Kilpatrick, showed that it was possible to engage students in the crucial activity of investigation even within the context of a traditional school. The experimental spirit in science curriculum with its emphasis on student investigative and reflective activity contrasted with the experience of most students whose science instruction consisted of textbook reading and recitation of facts and vocabulary.

The first systematic attempt at formalizing what should be taught and learned about science was done by the National Education Association's Committee of Ten in 1893. The work of the Committee of Ten standardized what was to be taught in the elementary and secondary schools. During the elementary years, children were to engage in "nature study," while in high school, students would study botany, zoology, chemistry, and physics with the goal of learning the facts and principles of those subjects in a laboratory setting. The work of the Committee of Ten was primarily about practice. If one were to operate a school, what would be done in the school?

World events of the 1930s and 1940s brought new imperatives for science education curriculum. Efforts to improve science curriculum were largely local before World War II. By the end of that conflict, U.S. citizens had become acutely aware of the power of mathematics, science, engineering, and technology and how important these disciplines were to the successful outcome of the war to the nation. The sense of urgency continued into the postwar world.

The first test of the atomic bomb by the Soviet Union in September of 1949 defined the scientific and technological nature of the competition between the United States and the Soviet Union. The rapid development of both an atomic and a hydrogen bomb by the Soviets reinforced the idea that preparation of U.S. students in mathematics, science, engineering, and technology was a national priority.

Jerrold Zacharias, a professor of physics at the Massachusetts Institute of Technology, and a member of the National Science Advisory Committee, focused on the apparent lack of preparation for university-level science work by his students when he and colleagues created the Physical Science Study Committee (PSSC) in 1956 to create a new physics curriculum. Although the perception

of an external threat mobilized resources (from the National Science Foundation among others) for curriculum development, the curriculum development work was done by first-rate scientific minds that were intent on ensuring that students would have the opportunity to learn science.

The model curriculum set by the PSSC was soon emulated by the Biological Science Study Committee (BSCS), CHEM Study, and a similar effort to support the study of the earth sciences. When the new programs were implemented, it became clear that teachers also needed to learn the new content and pedagogical skills to effectively teach in new ways. In part, this need was filled by National Science Foundation–funded summer workshops for teachers.

Elementary school curricula also emerged at this time. The development of the elementary programs also addressed the issues of providing science experience in classrooms that are not set up for students to work; for example, many classrooms do not have running water. The elementary programs were built around the development of understanding of the big ideas in science by giving young students experiences with observation, data collection, and the drawing of conclusions from evidence. The elementary programs all explicitly build the instructional sequence around a “learning cycle.”

The notable outcome of the elementary work was the development of a “kit-based” science curriculum. A science kit is an instructional unit including the materials and apparatus needed for the instruction that provides students with the opportunity to study science content in ways consistent with findings from cognitive sciences. A number of kit-based programs are in use. The use of science kits requires more professional development and logistical support than do traditional textbook-based programs. For example, kits need to be restocked with the consumable materials after each use. The National Science Resource Center at the Smithsonian has provided leadership to assist states and districts with the implementation of high-quality science curriculum as has the Association of Science Center Managers (ASCM). Following along, the commercial publishers have developed kit components to accompany their traditional textbook-based programs.

Barriers to the implementation of high-quality science curriculum include low levels of teacher

understanding of science content, state standards that attempt to cover too many topics, too little time devoted to authentic science instruction for many children, and instruction that fails to help students reevaluate their own preconceptions of natural phenomena.

## SCIENTIFIC MANAGEMENT

---

Scientific management is a systematic approach to organizing and controlling activities in business and industry that emphasizes efficiency as its primary goal. The brainchild of industrial consultant Frederick W. Taylor in the early part of the 20th century, scientific management became a movement that quickly spread to many fields and institutions in U.S. society. Educator Franklin Bobbitt was most responsible for introducing the approach to, and popularizing it within, the field of curriculum development.

Taylor’s most extensive discussion of the use of scientific method is found in his book *The Principles of Scientific Management*. In the first decade of the 20th century, Taylor became convinced that rampant waste could be eliminated from the industrial process and efficiency maximized through the careful application of four principles:

1. The development of scientific studies that analyzed the tasks of workers, the methods they employed, and the tools they utilized
2. The scientific selection of the workers in accordance with their potential to implement the scientifically validated methods

3. The education and training of workers in the methods
4. Careful planning and supervision that emphasized cooperation between managers and workers in the application of the methods in worker performance

In industry, these principles had the effect of separating planning through the analysis of task and tools from the execution of work. In education they had the effect of separating the process of curriculum planning from the activity of instruction.

As adopted and adapted by Bobbitt, these principles served as the foundation of what came to be called “scientific curriculum making.” This approach to curriculum development was introduced primarily through his two books *The Curriculum* and *How to Make a Curriculum*. In his work, Bobbitt also emphasized the elimination of waste by attempting to ensure that the greatest number of students would learn the maximum of amount of content and skills in the smallest amount of time.

This could be brought about, according to Bobbitt, by first analyzing the tasks and activities of adult life, and then ascertaining the current knowledge of students in regards to those tasks. The gap between the two would then become the source of objectives within the school curriculum. These objectives would serve as precise performance standards for learning that Bobbitt literally likened to the specific and exact physical standards for steel rails used by the railroad industry. The work of Edward Thorndike and others in the newly emerging field of psychological measurement had suggested that such precision was possible through educational testing.

The scientific management approach was appealing to members of the general public who yearned for more efficient uses of school funding. Proponents claimed that the precise measurements made possible by this approach allowed for clear comparisons in educational achievement between students, teachers, schools, school districts, and administrators. Educational and psychological experts were assigned the task of determining with some precision the most efficient method for teaching each standard. Like their counterparts on the factory assembly lines, teachers, in collaboration with

administrators/supervisors, were to be selected and trained in the use of these scientifically validated methods. Bonus plans were designed to reward monetarily highly efficient teachers and administrators. Inefficient educators whose students failed to meet the standards could be more easily removed. Advocates also envisioned that the plan would allow for reduced costs through increasing class size and decreasing the number of teachers needed. One of the most prominent advocates was the Newton, Massachusetts, superintendent of schools, Frank Spaulding.

Needless to say, some educationists were strongly opposed to this approach, not the least of whom was the educational philosopher John Dewey. Dewey and others objected to the application of the approach to education on several grounds. Some critics deemed it too mechanistic an approach to the practice of teaching and learning. Others suggested that it was born out of a need for certainty in a field that was inherently filled with uncertainty. Some complained that the approach devalued the work of teachers. Others suggested that the system failed on its own terms: They claimed that, with the large bureaucracy required for planning and supervision, the scheme was, in actual practice, too costly and inefficient.

## SCOPE AND SEQUENCE, IN CURRICULUM DEVELOPMENT

---

The design of a curriculum has an organizational dimension to it that accounts for what content

and skills should be taught and for how they should be instructionally presented over time. Among curriculum developers, the overarching organization of the curriculum is embodied in a concept known as *scope and sequence*. *Scope* specifically refers to the breadth of the curriculum—the organizing threads that constitute the skills and content that teachers are expected to include in their instruction. *Sequence* refers to how these skills and subject matter should be ordered. The two concepts work in synchronization because decisions related to scope have implications for sequencing and decisions related to sequencing have implications for scope. In each case, wider concerns about the coherence and continuity of the curriculum are at stake, as are the efficiency and educative power of the school experience.

Decisions related to the scope and sequence of a curriculum usually account for the developmental and maturational patterns of learners and a normative (state-directed) construction of what is worth teaching—what many teachers might see as the full range of skills, ideas, and content that need to be taught to learners at different stages of development. In this way, the scope and sequence of a curriculum provides teachers with a blueprint of age-appropriate learning outcomes. The end result is a carefully calibrated expression of skill development and subject matter knowledge that the teacher can usefully build lesson plans around.

Scope and sequence decisions are commonly worked out within grade levels, through a process known as horizontal articulation, and across grade levels, through a process known as vertical articulation. As a horizontal articulation concern, scope and sequence has to do with how school experiences offered early in an academic year will logically and coherently flow into experiences offered later in the year and to how the development of various skills (reading skills, thinking skills, and so forth) might change during an academic year to reflect increasing developmental capacities. Horizontal articulation also concerns itself with how grade level coursework is integrated and harmonized across subject matter. Thus, if calculus is taught simultaneously with physics, how do the two articulate? If the elementary school classroom is learning about early explorers in the social studies, how does such an undertaking articulate with the teaching of reading?

The vertical articulation of scope and sequence sets its analytical sight on cross-grade concerns. It is the tool used to build coherence in the educational experience of children during their entire school career. Thus, it asks how the teaching of, say, mathematics in 7th grade is related to the teaching of mathematics in 8th grade, or how mathematics instruction in the elementary school will provide a basis for learning mathematics in the middle school? In the science curriculum of the elementary school, vertical articulation concerns might result in a cross-grade curriculum that coheres around key principles and concepts, normally expressed as living things, earth and space, and matter and energy space. Similarly, reading instruction will follow a course of identifiable skills across grade levels related to, say, phonemic awareness, vocabulary development, narratives gauged by readability variables, and so forth.

Various curriculum scholars have identified some organizational principles that can be used to design the scope and sequence of curriculum content. George Posner and Alan Rudnitsky describe world-related sequences, which organize the content of the curriculum around the characteristics of space, time, or physical attributes. The use of a chronological sequence, which would likely be favored in, say, a history class, is an example of a world-related sequence because it uses the attribute of time (from earliest-to-latest) to organize the content. Sequencing content around spatial relations means that the organization of the content can be broached from the standpoint of, say, closest-to-farthest, bottom-to-top, or east-to-west. The vertical articulation of social studies education in the elementary school, for instance, commonly uses an expanding horizon design that starts with a focus on the self in the kindergarten, and expands outward (as children grow and mature) into community, town, city, state, national, and international affairs. The study of the food chain in science might be approached using a bottom (of the food chain) to top sequence, and the study of the regions of the United States using an east to west approach. Physical attributes, such as size, shape, and range of physical complexity, might also be used. So, in biology class, the study of simple cells could precede the study of more complex ones; the study of elements might be preliminary to the study of compounds in chemistry; the

study of the Civil War can be organized around the size of the major battles; and in geometry, lines might get taught before shapes.

But world-related sequences may not always be appropriate. Posner and Rudnitsky also point to the use of a concept-related approach, in which content and skills are organized around the structure of ideas. This could include approaches that sequence subject matter by logical prerequisites, by levels of sophistication, and by categories of class relations. A logical prerequisite approach is built on the assumption that some ideas are preliminary to others and need to be taught first. Skill-based content areas, such as reading education, mathematics education, and foreign language education tend to use this structure because of the highly defined and hierarchical nature of the skill structures. The content of the curriculum can also be patterned after the principle of sophistication, which gives justification to arranging or sequencing content by using a simple-to-complex or a concrete-to-abstract pattern, both of which demonstrate the idea of using simple tasks as subordinate parts to more complex tasks. *Class relations* implies a deductive (whole-to-part) pattern of sequencing that starts with class characteristics and moves to specific examples of the class. Thus, democracy is studied as a concept and followed by particular examples of working democracies. In science, the classification systems used to organize living things (amphibians, reptiles, mammals, fish, and so forth) might be studied first and then followed by examples of types representing each class.

Scope and sequence are the two main building blocks used to chart what the school intends to teach and the order in which they will be taught. One can find scope and sequence charts worked out for the design of textbooks, schoolwide or districtwide curricula, and even state (as well as national) content standards. The idea behind such organization is always led by two key questions: What is the proper sequence of content, skills (and other key learning attributes) that needs to be integrated into the school experience? And how exactly should this sequence be organized to advance the teaching and learning of children at varied levels of cognitive, social, physical, and emotional development?

## SECONDARY SCHOOL CURRICULUM

---

The secondary school curriculum was a definitive priority in the emergence and development of the field of curriculum studies in the United States. From the opening decades of the 20th century into the 1970s, the task of generating a viable theory of secondary education for a democratic society occupied a central place in the work of curriculum scholars. Since the 1970s, the curriculum field largely has abandoned interest in the secondary school curriculum per se for the pursuit of a conception of theorizing that often defines curriculum all-inclusively, as the course of one's life experience. Subsequently, discourse about and policy making directed toward the secondary school curriculum became dominated by academic traditionalists, policy entrepreneurs, and politicians. In what follows, a synopsis of the history of the secondary curriculum in the United States precedes a consideration of problematic aspects of current perspectives on the secondary school curriculum.

## History of the High School

During the 17th and 18th centuries, in the American colonies the curriculum of the Latin grammar school stressed formalistic instruction in Latin, Greek, and Hebrew language and literature for socially elite males. From the late 18th century into the 19th century, the academy movement expanded the secondary curriculum; subjects such as surveying, navigation, and bookkeeping, as well as English, modern foreign languages, geometry, and algebra, were offered often alongside the classics. This curriculum remained relatively constant, with local variation, for the remainder of the 19th century, as publicly supported high schools became the dominant form of secondary education, especially after 1870. By 20th-century standards, however, the curriculum of the late 19th-century public high school was relatively narrow, composed nationally as it was of only about 16 separate subjects. This curriculum evidently was suitable for the elite secondary student body that in 1890 represented only about 5.6% of the population of 14- to 17-year-olds.

With the expansion of secondary school enrollments during the first three decades of the 20th century and the invention of the comprehensive high school, the secondary school curriculum began to expand, especially in vocational offerings. By 1930, high school enrollments represented about 50% of 14- to 17-year-olds. By 1934, the secondary school curriculum included about 204 separate subjects nationally. At that time, approximately 62% of enrollments were in academic subjects and 38% of enrollments were in vocational subjects. This ratio of academic to vocational enrollments remained relatively stable until the early 1980s, after which time enrollments in academic courses steadily increased as enrollments in vocation courses slightly declined.

Both change and continuity over time can be discerned in the history of the secondary curriculum in the United States. Expansion of access to, enrollment in, and curriculum offerings of the secondary curriculum represent major changes over time. For example, as the proportion of enrollments in academic subjects remained stable, and the proportion of adolescents enrolled in high school expanded from about 62% of 14- to 17-year-olds in 1934 to about 94% in 2000, more

adolescents had access to the academic curriculum. The enduring dominance of the traditional academic, that is, college preparatory, program in the secondary curriculum represents continuity over time.

The field of curriculum theory and development responded to the changing demographics of the secondary student body. The year 1918 is often identified as a convenient starting point of the curriculum field in the United States because of the appearance that year of four influential publications: the Commission on the Reorganization of Education's *Cardinal Principles of Secondary Education*, Alexander Inglis's *Principles of Secondary Education*, Franklin Bobbitt's *The Curriculum*, and William Kilpatrick's "The Project Method." The content of these works represented the two central projects of the emerging curriculum field: identification of general techniques for curriculum development and generation of a theory of secondary education. During the next six decades, dozens of books and reform proposals and hundreds of articles appeared that attempted to develop and refine a theory and practice of secondary education suitable to a modern industrial democracy. These efforts engendered ideas and practices for secondary education such as the comprehensive high school model, general education, common learnings, core curriculum, the homeroom, and schools-within-schools, to name just a few.

During the 1970s, as the academic curriculum field began to shift its attention and energies toward the problem of understanding an all-inclusive conception of curriculum that transcended the institution of schooling, the problem of developing school curriculum all but disappeared from the agenda of curriculum scholars. The resultant void in theorizing about the secondary school curriculum subsequently was filled by reform proposals proffered by academic traditionalists, policy entrepreneurs, and politicians. Eventually, efforts to develop systematic, comprehensive conceptions of the secondary curriculum gave way to an eclectic parade of proposals for reforming particular aspects of the secondary school curriculum at the expense of viewing the curriculum as a whole.

Initially, these proposals, such as Ernest Boyer's *High School* (1983) and John Goodlad's *A Place Called School* (1984), came from educators with a

strong interest in curriculum, and addressed generally the problem of secondary education. Over time, however, proposals increasingly emanated from blue ribbon commissions, such as the National Commission of Excellence in Education's *A Nation at Risk* (1983) and the Task Force for Economic Growth's *Action for Excellence* (1983). Later, proposals increasingly sought to reform only particular dimensions of secondary education, such as workforce training, school size, choice, specialized subject standards, or high-stakes testing for accountability. In general, these proposals identified global economic competition as the catalyst for the reform of secondary education. With enactment of the Goals 2000: Educate American Act of 1994 and the No Child Left Behind Act of 2001, secondary curriculum policy formulation and adoption had been almost thoroughly arrogated by policy makers and politicians. Needless to say, the historic efforts of the curriculum field to develop a theory of secondary education for a democratic society were forgotten. Increased academic rigor became the panacea for any deficiency, real or perceived, in the secondary school curriculum.

### Current Perspectives

Although after the 1970s academic interest in the development of a theory of secondary curriculum waned, interest in the history of the high school waxed. Historical interpretations of secondary education that appeared since the early 1980s typically reflected the contemporary reform commitment to the traditional academic curriculum and seem to have interpreted the past through that commitment. At times, however, such interpretations do not square with the historical record.

Curriculum and educational historians tend, for example, to view secondary education in the late-19th century as something of the heyday of the U.S. high school. From characterizing the late 19th-century public high school as the "people's college," to depicting the 1893 proposals of the National Education Association's Committee of Ten as more democratic than the 1918 proposals of the Commission on the Reorganization of Secondary Education, historians tend to look favorably on this era, even presenting it as a model for the early 21st century. The reality that at that time high school education was intended for only

a small—considerably less than 10%—portion of the adolescent population contradicts depictions of the late 19th-century conception of the high school as more democratic than 20th-century conceptions, the latter of which typically called for secondary education for all youth. Indeed, the academic curriculum proposed by the Committee of Ten was tailored to an elite student body and expressly not envisioned for all youth.

As historians tend to depict the late 19th-century secondary curriculum favorably, they tend to depict the early 20th-century curriculum unfavorably. The invention of the comprehensive high school typically receives short shrift in historical interpretations of the era. Moreover, the comprehensive high school is almost exclusively associated with social efficiency—social control doctrine, which extolled the role of the school in fitting students into society in the interest of maintaining social control. Democratic aspects of the comprehensive high school, such as its express intent to simultaneously unify and serve the specialized needs of all adolescents, are typically played down. The fact, for example, that following World War II the comprehensive high school was adapted, in the name of educational egalitarianism, by countries across Western Europe, typically is lost on U.S. historians of secondary education. And the concept of social efficiency has become so closely associated with antidemocratic notions of social control that the prospect that the secondary curriculum can be about anything other than studying traditional academic subjects for their own sake—put another way, that the high school curriculum should directly address students' lives and the life of society—has assumed the status of anathema among many educational historians. As a result, curriculum initiatives of the past that departed from the traditional curriculum are either mostly ignored, as with general education and the core curriculum, or inaccurately denigrated, as with life adjustment education. Like reform proposals since the early 1980s, historical interpretations of secondary education in the United States have exalted the traditional academic curriculum.

And in practice, since the late 1950s, with the exception of the brief relevance movement around 1970, secondary education reform efforts—including the post-*Sputnik* structure-of-the-discipline projects, the curricular retrenchment of the late 1970s,

the academic excellence movement of the 1980s, and the standards and accountability movements of the 1990s and 2000s—have emphasized the traditional academic curriculum. Tradition, teacher certification requirements, preservice teacher education, and accreditation criteria have reified the traditional academic subjects into the one best secondary school curriculum. Research, too, particularly historical research, has taken the college preparatory curriculum for granted as the preferred form of secondary education. The pervasive problem of academic formalism, which is aggravated by high-stakes subject-focused testing, somehow escapes the attention of reformers and even researchers.

Meanwhile, as the number of academic courses that high school graduates complete has increased nearly 20% since the early 1980s, during that same period, surveys conducted by the Institute for Social Research at the University of Michigan have consistently found that students regard their high school studies as significantly less interesting, less meaningful, and less useful later in life. And as criticism of education in the United States increasingly focuses on comparative secondary school completion rates, the fact that most of the countries whose completion rates exceed that of the United States adapted the U.S. comprehensive school model, is overlooked. Curriculum students face a number of problematic issues in the practice of and research about the secondary school curriculum in the United States.

## SECULAR VALUES IN THE CURRICULUM: CASE LAW

---

Case law regarding secular values in the curriculum addresses the power of the state to teach nonreligious virtues or ideas. Litigation over the teaching of secular values tends to fall into one of two categories: conflict with religious values and student rights to abstain from participating. Some examples of secular values in the public school curriculum that have been contested by religious groups include gay and lesbian rights, science-based discovery, and morality derived from man instead of god. The debate about teaching secular values is at the heart of many controversial curriculum developments during the past 60 years. As scholars of curriculum studies track the interconnection of social change, scientific discovery, and public education, the clash between secular humanism and religious values remains a source of inherent tension.

Petitioners have unsuccessfully brought suit against the teaching of secular values under the argument that certain secular ideas are hostile to their religious values. Attempts to bolster this argument include casting secular values as a religion called secular humanism. The effort to define secular humanism as a religion has been largely unsuccessful despite the writings of some sympathetic judges, most notably Justice Antonin Scalia. If successful, petitioners could claim that the teaching of secular values constituted the promotion of religious values thus violating the establishment clause of the First Amendment. A broader argument against secular values in the curriculum claims that the teaching of any values that do not include a deistic perspective promotes the “religion” of secular humanism over other religions. The argument continues to claim that the only way to avoid this violation of the Establishment

Clause is by including religious perspectives in the curriculum to be taught with secular perspectives. It seems inconsistent with existing case law, however, that even a successful claim of secular humanism as a religion would allow religion specific instruction to be constitutionally taught. Presumably, the school would be compelled to create a neutral forum by which it would be expected that the range of ideas presented to students would be encompassing enough to avoid promoting any one religion. However, teaching the values of one religious faith in concert with secular values falls far short of the neutral forum standard established by the Supreme Court for political speech. Moreover, it is unclear that the court would accept the neutral forum standard for religious speech. The Court has yet to rule on establishing a neutral forum for religion in schools.

Efforts to teach creationism or intelligent design as part of the evolution curriculum has led to litigation that is central for defining case law on the issue of secular humanism as a religion. In *Epperson v. Arkansas* (1968), a state statute prohibiting the teaching of evolution was struck down by the Court. In response, several statutes were written promoting a “balanced treatment” of evolution that included both an explicit disclaimer in the curriculum that evolution was an unproven theory and a biblical perspective on the origin of man. The “balanced treatment” curriculum was found to violate the Establishment Clause of the U.S. Constitution and eventually the U.S. Supreme Court ruled in *Edwards v. Aguillard* (1987) that creation science was unconstitutional. The latest efforts to challenge teaching evolution casts creationism as the intelligent design of a creator. An interesting element of the intelligent design proposal is the claim that the “creator” is not necessarily a specific deity. By making a prima facie argument that the creator may not be God, the petitioners in *Dover v. Kitzmiller* (2005) were essentially aligning intelligent design with the secular curriculum. The Court in *Dover* found that intelligent design was not a secular theory and was in fact a progeny of creationism.

Teaching patriotism in the public school curriculum is both common and supported by case law. However, compelling a student to demonstrate allegiance or support of nationalistic ideals

as part of that curriculum is unconstitutional. For example, in the early years of World War II, several states and school districts enacted regulations that promoted a curriculum of nationalism. The West Virginia State Board of Education followed suit in 1942 with a measure that prescribed a curriculum intended to teach, foster, and perpetuate “the ideals, principles, and spirit of Americanism.” As part of the curriculum in West Virginia, teachers and students were required to participate in the flag salute and pledge each day. To refuse was explicitly deemed insubordinate by the board regulation that stated that those who did not salute the flag would be “dealt with accordingly.”

The Court in *West Virginia State Board of Education v. Barnette* (1943) rejected the right of the school board to impose an allegiance standard as part of a broader citizenship curriculum. The majority opinion stated that the curriculum itself (i.e., teaching democratic citizenship) added additional importance to the protection of students’ constitutional freedoms. In an oft-cited rebuke of the West Virginia School Board’s actions, Justice Robert H. Jackson wrote, “If there is any fixed star in our constitutional constellation, it is that no official, high or petty, can prescribe what shall be orthodox in politics, nationalism, religion, or other matters of opinion or force citizens to confess by word or act their faith therein.” Later court cases would continue to support this balance between teaching secular values and requiring allegiance to those values. This is specifically true in regards to politics and nationalism.

Students may not be punished for unpatriotic views, and as long as their actions do not create a substantial disruption, they may express other views. For example, in *Holloman v. Harland* (2004), a student was paddled as punishment for raising his fist in silent protest during the pledge of allegiance. The circuit court found that the school’s actions were in violation of the student’s First Amendment right to free speech. Subsequent opinions have reinforced the idea that schools may not force patriotism.

## SEMIOTICS

---

Semiotics is the study of sign and symbol systems. Semiotic analyses explore the ways in which meaning is constructed and understood. Semiotics includes written and spoken language as sign systems, but, unlike linguistics, is not limited to language. Images, sounds—both natural and linguistic, gestures, or associations of any two or more of these—can all be parts of sign systems. For the curriculum field, semiotic studies tend to be focused on curricular language and media, institutional environments (e.g., the hidden curriculum), and visual images. From the standpoint of semiotic theory, analyzing words, images, gestures, and situations is always an interpretive act; there is no such thing as a “literal reading.” Hence, all sign systems, as entities to be “read” or interpreted, regardless of form, may be referred to as “texts.” A semiotic standpoint runs contrary to any assumption that there is a discernable or final meaning to be obtained for any particular text, including, for example, religious texts, school textbooks, “best practice” teaching methods, or state curriculum standards. Similarly, semiotic theory challenges any notion that the curriculum can be an innocent conduit for transmitting academic knowledge. As such, semiotic analyses might undermine arguments that curriculum can be designed and implemented as an objective scope and sequence of any particular discipline, or that it can be fairly and accurately evaluated by student performance on standardized tests.

Arguably, the most important theorists of semiotics to the contemporary curriculum field are Charles Sanders Peirce (1839–1914) and Ferdinand de Saussure (1857–1913). Saussure proposed a dyadic structure in which a *signifier* (a word or

phrase) relates to a *signified* (a mental concept). To illustrate, the marks *c-a-t* placed together become the *signifier* for the concept *cat*, the *signified*, that evokes among English language speakers a four-legged furry animal. But, Saussure asserts, the relationship between the *signifier* and the *signified* is an arbitrary one, with no necessary connection between the word and the concept. That is, any number of other words could just as well have been chosen to signify cat. And indeed, there are many other words to signify the animal in languages other than English. What is more, the meanings attached to words (signifiers) often change over time with changes in ideology and other aspects of culture. Language, for Saussure, *differentiates* concepts that might otherwise be experienced as a continuum. For example, as one experiences the color spectrum moving through shades of blue, there are no lines drawn at points of change; it is only words that enable *distinctions* in the experience. Saussure’s theorizing was limited to linguistics, but many have transposed this system of thought onto nonlinguistic sign systems, making it a theory of semiotics.

For Peirce, semiosis involves the interaction among three subjects: the *sign*, its *object*, and its *interpretant*. Peirce’s *sign* is most analogous to Saussure’s *signifier*. Peirce’s *object* is that which is *signified*. Hence, smoke would be a *sign* for the *object*, fire. The *interpretant* might be characterized as the understanding (interpretation) one has of the *sign-object* relationship. For Peirce, a sign signifies only through its being interpreted; hence, each part of the triad is essential to signification. And this signification is not closed to itself, but is a sign process. Peirce’s *interpretant* is itself again interpreted and so becomes a *sign* in relation to yet another *interpretant*, in endless semiosis.

The famous painting by surrealist artist, Rene Magritte, *This is not a pipe*, provides an oft-cited example of the power of semiotic analysis to illuminate the problem of representation. The artist inscribed the title in French across the bottom of this apparently realist representation of a pipe for smoking. Magritte challenged the viewer to recognize the difference between an actual pipe and a representation of a pipe, as well as the difference between a string of words and their referent; in so doing, he called attention to the arbitrariness of the sign system.

In curriculum studies, an example of a semiotic analysis might be found through examining the discourse around high-stakes standardized testing. A particular *test score* becomes the *sign* (Peirce) or *signifier* (Saussure) for “achievement,” or even for “intelligence.” A semiotic understanding of this relationship would challenge the transparency assumed from *signifier* to *signified*, or *sign* to *object*. Where transparency is assumed, there is no recognition of the arbitrariness of the sign system. Either the *signifier* is assumed equivalent to the *signified* (erasure of difference which is what enables language to function), or the *sign* is assumed equivalent to the *object* (erasure of interpretation which is what enables meaning to be made).

## SERVICE-LEARNING CURRICULUM

---

Service-learning has become a significant element of curriculum at the elementary, secondary, and postsecondary levels. It is distinguished from community service in that service-learning is credit bearing; it involves a reciprocity between those serving and those being served to satisfy an identified community need, either at home or abroad; and it is integrated into the curriculum content area. Service-learning is important to the field of curriculum studies because of its link between theory and practice, and the opportunity it affords to examine the cultural, political, and social underpinnings that influence the lived experiences of those served. A look at service-learning involves an

examination of the potential it holds, as well as the obstacles sometimes encountered, for linking theory to practice; the role of collaboration between those serving and those served; ways to maximize the reciprocal nature of the process; and means by which to effectively integrate the service-learning experience into the content area being studied such that students develop a greater understanding of the significance of the role of civic engagement in the service-learning experience.

One of the main goals of service-learning is to provide learning opportunities for students outside the classroom in ways for which the classroom is not conducive. An example is students in a college teacher education course working with children in the community in some capacity. This might involve tutoring or coaching, for instance. The idea, in this example, is to allow students to engage in hands-on learning that both reflects and informs pedagogical concepts learned in the classroom. In some cases, this experience can affirm those concepts learned in the classroom, particularly when the site served, for example, subscribes to the same pedagogical philosophy and techniques learned in the classroom, or when students are allowed a significant degree of autonomy to work with the children in ways that they have been taught in the classroom. Conversely, there are situations in which students find themselves grappling with techniques and methods that do not align with those espoused in the classroom, sometimes techniques that are in direct opposition, in fact, to those taught in the classroom. Service-learning can involve one-on-one working with those served or working in cooperation with others to serve one or more individuals.

An integral component of service-learning is a collaborative effort by those serving and those served to identify and address the need(s) to be served through the service-learning process. This entails those serving being particularly sensitive to what the agencies/institutions request, and both parties entering into dialogue to determine if those needs can be addressed and met by those interested in serving. For example, although those serving might believe that the needs articulated by the respective agency/institution should be addressed in a particular way(s), it is not their place to impose their beliefs and practices on those served without the affirmation and input of the group(s)

served. In this way the process is cooperative, with both parties working toward meeting the identified needs. Likewise, the agency/institution served should be fully involved in any assessment regarding the effectiveness of the service.

The relationship between those serving and those being served is also reciprocal. That is, the service-learning experience serves a need for those serving, and it serves a need for those being served. The addressed need of those serving is additional, hands-on learning to supplement the classroom experience. The need of those served depends on the particular agency/institution.

Service-learning affords students the opportunity to examine the cultural, political, and social underpinnings that affect the lived experiences of those served and to become actively involved in addressing those issues in ways that contribute to a more democratic society. Spoma Jovanovic discusses this from an ethical perspective that entails examining how individuals ought to live their lives and posits that to do this, it is necessary to acknowledge the existent social inequities and our responsibilities as citizens to respond. This, as Jovanovic notes, involves students questioning the extent to which they are complicit in enabling systemic inequities or how they can act to effect change toward a more egalitarian society. Such civic engagement is fostered by reflection and analysis that is incorporated into the curriculum. Integration of the service-learning experience into the content area(s) under study allows students to draw links between theory and practice. Returning to the example of students in a college teacher education course, this link becomes apparent when students reflect on their service-learning experience in light of the concepts addressed in the classroom that facilitate critique of the inequities in society. Reflection, therefore, becomes significant to the service-learning process. Julie A. Hatcher and Robert G. Bringle discuss the importance of reflection as a means to re-create assumptions, develop new frameworks, and construct perceptions that affect future action. If students fail to contemplate their service-learning experience, Hatcher and Bringle note, their service activities might reinforce stereotypes, uphold presuppositions, and fail to critically steer students to future action.

Hatcher and Bringle discuss a variety of forms that reflection can take and note that it must

involve analysis and not mere recitation of service activities. They suggest personal journals, presentations of ethical dilemmas encountered in the service-learning experience, structured class discussions, and directed writings as means to reflect analytically. In addition, they note that poetry, painting, and storytelling can result in moving accounts of the personal impact that the service experience has on students. Deborah Biss Keller and Robert J. Helfenbein discuss how art forms were used in a service-learning class taught by the author. They elucidate the results of art as a means of reflection, describing how some students engaged in critical analysis of the underlying systemic forces in relation to their service-learning experiences to a greater extent than did other students.

The actions that students can take as a result of their engaged critical analysis include writing to the editor of a newspaper(s), writing to legislators, lobbying, and so on. Rick Battistoni discusses the importance of experiential learning to democratic communities past and present. He notes that students need to see the link between issues of interest to them and reasons to become publicly engaged, as well as practice in the democratic processes. Service-learning provides such an opportunity for students.

## SEXUALITY RESEARCH

---

The broad area of sexuality research includes studies pertaining to the biology of sex and sexuality as well as social constructions of gender. It encompasses such topics as child and adolescent sexuality, sexual orientation or sexual preference, gender identity, the body and body image, and sex education and reproductive health, each of which can be discussed in terms of biology as well as social constructions. Sexuality research intersects with and draws on such areas of study as feminism, gender studies, queer studies, cultural studies, and psychology and medicine. Sexuality research also engages larger questions of how gender and sexuality are understood and enacted in different social contexts. For instance, “Western” constructions of heterosexuality and homosexuality may not be applicable in Asian or African cultures. This area of research proves most important to the work currently being done in the field of curriculum studies.

Sexuality research falls on both sides of the “nature vs. nurture” debate. Research that draws on biology to frame its questions may focus on established categories of gender—for instance, such binaries as female and male. Sexuality research that emerges from the frame of social construction generally engages more fluid interpretations of sex and gender—for instance, rather than viewing gendered identities as biologically determined, such research may construe them as performance. Theoretical work pertaining to the social construction of gender, which informs such scholarship, critiques essentialist and deterministic approaches, emphasizes the fluidity of gender and sexuality, and engages the intersections of race, class, culture, gender, and sexuality in historical and geographic contexts.

As in the broader area, sexuality research pertaining to education and curriculum emerges from perspectives rooted in biology and from theoretical approaches that engage social constructions of gender. In recent years, research in the education field has focused on such issues as discrimination based on gender and sexual orientation, the pros and cons of same-sex schooling, and gender(ed) representations in curriculum,

including the representation of lesbian, gay, bisexual, and transgender (LGBT) youth and families. For instance, with regard to K–12 schooling, scholars have examined how schools privilege boys and “fail at fairness,” offering unequal education to girls. Just as sexism shapes the hidden curriculum, so, of course, does heterosexism. Scholars and researchers have also documented and interrogated heterosexist bias and the effects of homophobia in curriculum and teaching. For instance, it is well established that a majority of LGBT students encounter harassment at school and that the suicide rate among them is high.

Educators have developed a number of curricular and pedagogical resources for K–12 settings to address some of the issues that sexuality research has brought to light. For instance, from specific teaching strategies outlined in publications such as the ones available from Milwaukee, Wisconsin-based publisher, Rethinking Schools, to films for educators (such as *It’s Elementary: Talking About Gay Issues in School*) to the establishment of gay-straight alliances in schools, educators are trying to address heterosexism and homophobia. Furthermore, popular media (such films as *Boys Don’t Cry* and *Billy Elliott*) and books representing the voices and stories of LGBT youth and young people who do not fit predetermined notions of gender are also available to educators, as are resources from such organizations as Parents, Families, and Friends of Lesbians and Gays (PFLAG) and Gay, Lesbian, and Straight Education Network (GLSEN).

In the field of curriculum studies, sexuality research has focused on autobiography and narrative(s) and has drawn from queer theory, feminism, gender studies, philosophy, poststructural and postmodern theories, cultural studies, and, more recently, transgender studies. Curriculum scholars have examined historical and contemporary contexts to analyze the intersections of race, gender, culture, and sexuality. This work is relevant to rethinking multicultural education and teacher education.

## SMITH, B. OTHANEL

---

B. [Bunnie] Othanel Smith (1903–1989) was a teacher, school administrator, professor, and curriculum theorist. Smith's areas of influence include curriculum development, teacher education, teacher knowledge, educational philosophy, and educational measurement. Notably, Smith is known for advancing the concept of critical thinking, promoting the study of logic within the profession of teaching, and arguing for a focus on pedagogy in teacher education curriculum.

During the early years of his career, Smith worked in Florida high schools as a science teacher and principal. He was overwhelmed by disparate curricular models that he and other teachers encountered as part of their daily practice. Frustrated with the sheer number of models such as these, Smith rejected the idea that any one formula could prove to be a panacea for curricular problems. Consequently, he devoted his academic life to discovering what skills teachers needed so that they might create their own solutions for improving school curriculum. Graduating from the University of Florida with a BS in education, Smith later enrolled in the graduate program at Teachers College, earning a MA in 1932 and a PhD in 1938. Smith's doctoral dissertation focused on educational measurement; specifically, he investigated the logic of assessment. This research sparked Smith's lifelong interest in the relationship between logic and teaching. Teachers, Smith later

theorized, use logical reasoning constantly during the act of teaching—for example, when they define terms, explain concepts to students, or evaluate a particular behavior. He saw logic as preferable to psychology; rather than construing teaching as a psychological process, Smith argued that educators should view teaching as a logical process.

Smith accepted a job at the University of Illinois in 1937, where he began to shape and refine his conception of teaching. He defined teaching as a series of actions designed to result in learning, while acknowledging that the act of teaching may be performed differently within various cultural contexts. Drawing on the work of Harry S. Broudy, his friend and colleague at the University of Illinois, Smith embraced the interpretive use of knowledge. Smith asserted that learning should focus on teaching students the skills needed to reason and think critically so that they might make wise decisions later in life. Educators who taught students the process of thinking and stressed the utility of content, Smith believed, were preferable to classrooms that targeted the socialization of the learner. Also during his time at Illinois, Smith authored what might be his most famous work, *Fundamentals of Curriculum Development*, with Illinois colleagues William O. Stanley and J. Harlan Shores. The text echoed Ralph W. Tyler's four-step procedure for selecting curriculum content. The book helped to promote the study of curriculum as a subject in teacher education programs and influenced the work of curriculum development scholars for several decades.

Smith authored *Teachers for the Real World*, published by the American Association for Colleges of Teacher Education. Supported by the U.S. Department of Education, the publication became foundational for programs sponsored by the government. Smith believed that university curriculum designed for preservice teachers often focused too heavily on theoretical, conceptual coursework typically found in foundations classes. Although he acknowledged that a general knowledge of such topics as human learning and social development was important for educators, Smith believed that “real world” curricula for teachers should focus chiefly on pedagogy. In *Teachers for the Real World*, Smith and his collaborators, Saul Bernard Cohen and Arthur Pearl, were the first teacher

educators to champion the idea of preparing teachers through protocol materials. Protocols were audiovisual recordings of school-related scenarios (classroom, playground, home, etc.) that Smith believed provided a more direct relevance to classroom practice than lecture formats typical to most teacher preparation programs at the time.

Smith encouraged universities to use protocol materials and redesign teacher education curriculum to stress practical classroom application and pedagogical tasks. These tasks, he asserted, would more appropriately synchronize with what teachers were expected to do within the classroom: specifically, instructional tasks (questioning, assessment), management tasks, collective tasks (committee work), staffing tasks, interviewing tasks (working with principals, parent collaboration), programming tasks (curriculum development and instructional planning), and community tasks. To devote valuable teacher preparation time to coursework that did not focus on pedagogy, Smith reasoned, would be a great disservice to future teachers. To emphasize his conviction, Smith attended to semantics in his lectures and his writings. For example, he dichotomized teacher education curriculum as either “pedagogical” or “nonpedagogical” (rather than “pedagogical” or “academic”) and embraced the word “training” rather than “education” in regard to teacher preparation.

## SOCIAL CONTEXT RESEARCH

---

Social context research is a broad and vital endeavor in the field of curriculum studies. In general, social context research within curriculum studies entails two major perspectives. One is that any attempt to understand educational phenomena requires an analysis of the broader context within which these phenomena are situated. The second is that research in curriculum studies typically seeks to illuminate the role of the social context and in viable ways to transform it in directions conducive to sustaining personal freedom and social justice. After describing several characteristics of a social context, this entry addresses three central features associated with understanding and transforming the social context with a curriculum studies framework.

### Social Context Is Ubiquitous and Multidimensional

Consider a Russian nested doll. Broadly conceived, it can represent the notion that one’s place in the world is inherently embedded in—and simultaneously shaping of—other forces that range in proximity and visibility. Whether the forces function for or against us, we unavoidably enter a world with stacked, that is, preexisting material conditions that shape our options and influence our conduct and consciousness.

These conditions are multiple in nature, involving a complex gestalt of historical, political, cultural, economic, social, intrapsychic, and idiosyncratic dynamics. To illustrate, consider the following hypothetical situation. A researcher wants to understand why a particular eighth-grade White male, Sean, bullied a Black male classmate, James. Selected perspectives that the research process might reveal include the following: Like his twin brother, Patrick, Sean is one of the tallest and strongest students at his middle school. Admired as a leader by his tight group of friends, he’s a hard-working center on the school’s basketball team. His playing time has recently been reduced because of several Black transfers whose overall athleticism clearly outshines his. Sean is a below-average student who discourages quickly when he meets academic challenges. His policeman father is a Vietnam

veteran, a Rambo fan, and a recovering alcoholic who abused his wife physically and emotionally upon his return from Vietnam. Initially sympathetic to her husband's traumatic war experience, Sean's mom increasingly stood up to the abuse and is a major catalyst behind his dad's turnaround.

James is physically small but possesses sizable wit, intelligence, and academic capability. The only child of two professors, he is reserved in manner, though his insightful and sarcastic sensibilities are occasionally on display in class discussions.

Historically 99% Caucasian, the middle school has witnessed a 15% increase in Black and Hispanic enrollment over the last five years. Incidence of bullying has risen 5% during this period. The school board has debated a zero tolerance policy but by a narrow margin has rejected such a policy, publicly expressing its fear of inflexibility toward unforeseen, extenuating circumstance. Multicultural sensitivity workshops for teachers, staff, and students were instituted four years ago, but a recessionary economy has created budgetary constraints, limiting these required workshops and substituting more sporadic, informal, voluntary discussions. It is known that the school principal views these sessions as well-intended but frustrating and unproductive.

The point of presenting this scenario is not to solve it, but, in concert with the reader's own interpretative framework and imaginative analysis, to suggest that to approximate a rich understanding of the processes at work culminating in Sean's (and not Patrick's) behavior around bullying, a host of multilayered, contextual factors must be explored, illuminated, compared, and synthesized. To do so well, curriculum studies researchers ideally seek to approach their work with several key understandings and commitments, explicated in the subsequent sections.

### Implications for Educational Research

In the U.S. context of a significant school dropout rate, heightened youth crime, intensified global competition, relatively poor achievement test scores, and broad-based skepticism about the government's regulatory responsibilities, state supported schools are often seen by policy makers and the public as part of the problem, rather than part of the solution. Compound this perception of

failure with dramatic developments in biomedicine (various "miracle" drugs for combating cancer), engineering (a prototype car that gets 80 miles/gallon), and physics and technology (the stopping of atoms, the discovery of planets), and it's no wonder that, with varying degrees of thoughtful awareness, certain taxpayers, legislators, and social scientists trained in positivist methodologies might come to idealize the research protocols and benefits of the "hard" sciences, elevate this paradigm to the status of exemplar and crave comparable definitive results from educational research in matters of paramount practical importance to teaching and learning.

Ironically, social scientists rooted in the "realist" tradition associated with qualitative methods of inquiry recognize that much educational research is doomed to be disappointing not because, in the case of realist research, it lacks rigor, validity, or practicality, but because by the very nature of most research in education, contingency is king.

Several interrelated considerations are germane to this perspective. Realist social researchers are looking to understand what's "really going on" in the context being studied. They are not satisfied with just documenting the *effects* of systematically manipulating variables, a focus characteristic of (quasi-)experimental research designs and termed *causal description*. Rather, realists are committed to seeking understanding of the local *events, processes, or mechanisms* that catalyze changes in relationships among studied variables, a focus conducive to qualitative inquiry and termed *causal explanation*. Realists argue that social context is a fundamental, not merely a (co)incidental element in causal explanation. That is, the context is inextricably connected to the events or processes the researcher is seeking to explain. For example, in the bullying case of Sean cited earlier, the realists' claim would be that an attempt to control for or factor out any of a host of dynamics (Sean's family relations, his academic performance and associated self-esteem, the local history of White exclusivity, the school's policy on zero tolerance, etc.) could be akin to creating a different and now hypothetical context than the interactive one that was "actually" operating. An essential effect of such manipulation would be to eliminate rather than to illuminate the phenomena being studied, blurring rather than sharpening understanding,

creating conditions for less not more valid provisional conclusions.

Another core feature that characterizes, compels, and complicates social context research in education is the concept-dependence of social phenomena. Understanding what the practices, roles, and relations actually are is contingent upon how they are defined by participants in a particular setting. Thus, it is insufficient to study behavior alone because what behavior means depends on the intentions, beliefs, values, and volitions, that is, the interpretative frame of the various actors involved in a given context. Although the process is labor intensive, systematically eliciting and examining the “inside” view of research participants becomes a vital ingredient in better understanding the dynamics of the research situation. By contrast, “black box” research that does not investigate and reveal participants’ perspectives threatens to consign itself to problematic degrees of speculative causal explanations.

As suggested earlier, curriculum studies realists engaged in qualitative and alternative methods of inquiry are no strangers to threats to their professional credibility. Although at their best, they need make no apologies for the rigor and validity of their methodology and for the power of their findings and perspectives, for many reasons, realists nonetheless confidently emphasize the provisional nature of warrantable conclusions. Contexts are ceaselessly complex and changing. Inquiry into interactions is inevitably encapsulated and incomplete. Self-interpretation is fundamentally fractional and fallible. At the end of the day, omniscience is inaccessible and overtures to its achievement outrageous. With an infinity of certitude, curriculum studies realists can claim that there is always more to know, to understand, to do. Hinted at here, these perspectives raise challenges and opportunities that are further addressed in the next section.

### The Dynamics of Social Context Research

Consider the famous picture that from one vantage point appears as the face of an old woman yet from a different viewing appears as a well-dressed young female. Which perception is the “correct” one? In a fundamental sense, both are correct and both are incomplete. Though different, neither is distorted and both are needed to realize the potentially

legitimate interpretive realities that exist in this context. In a significant sense, then, truth is perspectival and hence multiple and situated, not absolute, unitary, or context-independent.

Social context researchers at their best deal with these dynamics in a similar fashion as instant replay in football. Instant replay draws on multiple angles and composite picture assessment to seek the “truth” around a referee’s disputed call. Sometimes no one angle holistically reveals a definitive conclusion, but several partial vantage points, in concert, do. And sometimes, however viewed, no angles yield an unqualified confirming or disconfirming perspective, and the initial judgment of the referee stands.

While realist social scientists seek to understand the truths as research informants perceive them, the previous analogies translate into two ethically grounded professional practices. One is for the researcher to be transparent in communicating one’s ideological and interpretative perspectives to both research participants and consumers. This transparency is meant as a cautionary alert and critical corrective to both kinds of blinders that come with the partiality of one’s position; that is, its unwitting incompleteness and its probable self-serving, marginalizing, partisan bias. A complimentary practice, noted by Donna Mertens, is the synergistic use of mixed methods to augment or triangulate the analysis of data in the interests of expanding access to diverse perspectives, reducing reductionism and, more generally, offsetting the limitations of any one methodological approach.

This welcoming stance toward external and internal critique invokes the instructive culture of a team of rivals. Whether the reference group is a political administration, a research community, or a school district, in such a culture, opposition is characteristically seen as opportunity not onus, vitality not villainy, conceivably course correcting not collaboration corroding. The spirit animating this culture is designed to function as an antidote to power’s perfect storm of arrogance, and ignorance, self-serving activism, and status-quo maintenance.

Unfortunately, within the 21st century’s dominant political context that has shaped standards for research agendas and school practice—the George W. Bush administration’s No Child Left Behind Act of 2001 and the Education Science Reform Act of 2002—curriculum studies social

context researchers, fulfilling one of their central roles as critics of orthodoxy (see the next section), saw little evidence of this culture in operation. On the contrary, what predominated in researchers' views was conformist zealotry around narrow conceptions of scientifically based research, a misguided, underfunded and punitive preoccupation with high-stakes testing as the gold standard measure of academic achievement, and "web scrubbing" of ERIC digests unsupportive of Bush initiatives. This agenda created an educational atmosphere where authority tethered truth, ideology imperialized information, and, contrary to slogan, school systems were pressured to strategically leave children behind in a form of educational triage to receive respectful recognition of adequate or distinctive progress.

In the "science wars" of this period, not unlike the preceding culture wars, distrust between the contesting camps was thick, generosity and tolerance thin. Seen variously by their critics as obstructionist and outsiders, unpatriotic and unproductive, curriculum studies social context researchers insist on advancing what they consider ethical imperatives of their work. The final section of this entry selectively presents this set of perspectives.

### Toward a Transformative Paradigm of Research

Curriculum studies scholars researching and writing from critical race, feminist, Foucauldian, humanist, Marxist, postcolonial, poststructural, psychoanalytic, and queer interpretative frames tend to converge on the general themes that educational research and practice should better investigate the systemic and internalized inequities that significantly structure the lives of historically marginalized groups. These scholars have identified those remarkable resources that contribute to the subaltern's resilience and transcendence. The remarkable resources that contribute to the subaltern's resilience and transcendence. Three dimensions are integral to a transformative paradigm of research directed toward social justice. These are an examination of power dynamics in the multiple contexts of the subaltern's lives, a collaborative relationship in which the subaltern have a voice in defining the research questions and accommodating the research methodology to suitably respond

to relevant cultural complexities, and a praxis orientation that seeks to link research findings with practical actions that concretely enhance the quality and social justice of the subaltern's lives.

In a contextual and activist mode compatible with Mertens, Jean Anyon argues that economic reform is a vital prerequisite to urban school improvement. For her, essential dimensions of a vital new paradigm of educational research would include documenting and describing oppression and the practices of the powerful as well as studying relevant social movements and the conditions under which student and teacher activists connect with these movements in the interests of school reform.

### Concluding Comments

Steeped in a history of structural analysis, humanist sensibilities, and activist commitments, William Ayers recommends three themes pertinent to curriculum studies researchers engaging in social context–social justice research. These are opening our eyes/seeing the person, challenging orthodoxy, and linking consciousness to conduct. These themes permeate a set of six questions he encourages prospective researchers to explore to enhance the twin transcendent goals of enlightenment and emancipation. Ayers' questions, appearing in his essay entitled "Trudge Toward Freedom," serve as a fitting conclusion to this entry.

- What are the issues that marginalized or disadvantaged people speak of with excitement, anger, fear, or hope?
- How can I enter a dialogue in which I will learn from a specific community itself about problems and obstacles they face?
- What endogenous experiences do people already have that can point the way toward solutions?
- What is missing from the "official story" that will make the problems of the oppressed more understandable?
- What current or proposed policies serve the privileged and the powerful, and how are they made to appear inevitable?
- How can the public space for discussion, problem posing, and problem solving be expanded?

## SOCIAL CONTROL THEORY

---

Social control theory in curriculum studies refers primarily to the question of how what is taught in schools limits or creates possibilities in students’ lives and serves particular interests in broader society. Connecting to both the new sociology of knowledge movement and the reconceptualization of curriculum theory of the 1970s, social control theory sees curriculum as inclusive of much more than curriculum design or issues of scope and sequence and points to the ways in which curriculum decisions have deep impact on the lives of children in society. This entry describes the historical

development of ideas related to curriculum and social control, delineates ways in which curriculum theorists have described its operation, and concludes with contemporary thinking on its applicability to educational research.

### Historical Development of Curriculum and Social Control Ideas

Certainly, questions of curriculum have dominated scholarly work in education from the time of the Ancient Greeks. The framing question of “what knowledge is of most worth” can be seen in thinkers such as Plato and Aristotle continuing on into the present day. Contemporary scholars suggest that the distinction between who has the power to make these decisions concerning the value of knowledge and who does not in and of itself points to issues of social control. As differing notions of which segments of the population should be afforded educational opportunity arose throughout history, debates ensued as to *what* should be taught to *whom*. So then, issues of social control in curriculum reside closely to fundamental questions of the purposes of education.

Social control theory begins in a critique of the highly influential social efficiency curriculum. Social efficiency theorists believe that the purpose of school is to sort the nation’s youth into future occupations according to their abilities. As this focus on the tight connections between schools and the workforce drives curriculum thinking within this model, an inequitable economic system based on competition necessarily creates a system of inequitable educational opportunity. Taking their lead from the scientific study of industry, perceived waste in the educational system becomes a target for reform. The sorting of students into particular tracks or curricular paths seems to be logical as part of the pursuit of efficiency in aligning schools to the needs of society. How gender, race, or class might affect these seemingly objective processes rarely made it into the equation.

The rise of social efficiency’s prominence in the U.S. educational conscience can be traced to the upheaval that U.S. citizens experienced in the second half of the 19th century when immigration and industrialization collided. An influx of immigrants from Southern and Eastern Europe into

post-Civil War United States dramatically changed the demographics of a rapidly changing country, and with those changes came heated debate as to the role of education. Until that point, the most U.S. residents emigrated from Northern or Western Europe, and the new wave of immigrants were often framed as savage, genetically disposed to be ignorant and destined to fill the lower classes of U.S. society. Concurrently, the late 1800s brought the dawn of the Industrial Age, leading to the development of large urban centers that contrasted sharply with heretofore agrarian and provincial U.S. communities. Combined, the ethnically shifting population and new urban centers posed, for many U.S. citizens, a threat to the society to which they had grown accustomed. In the views of many curriculum scholars, the new immigrants who were flooding into urban centers for the promise of industrial employment required socialization to U.S. values and customs to maintain or regain order.

### Curriculum Theorists on Curriculum and Social Control

The advances in technology that spurred industrial growth also bred a new reliance on and faith in science. Thus, emerging fields of study such as sociology and psychology sought scientific processes and empirical evidence to verify their observations and bring validity and broader application to their fields. Sociologist Edward A. Ross was one such man. His fear of the U.S. demise at the hands of the new immigrants coupled with his enthusiasm for the new science of sociology led to the development of one of the earliest theories of social control in a book published in 1901 and aptly titled *Social Control*. Ross's theory included two types of social control, direct and indirect. Direct control relied on the application of sanctions, whereas indirect control relied on suggestion, emotion, and judgment of two forms, ethical or political. Forms of ethical social control appeal to individual's sentiments such as public opinion, suggestion, and religion. Political forms of social control, on the other hand, depended on the ability of those with the majority of political power to regulate the affairs of the masses. Examples of institutional political control include the law and educational system. Ross believed that in a

homogenous society, there was no need for political forms of control. However, in the heterogeneous society that Ross perceived before him, political forms of social control functioned to maintain order. When publishing his own theory in *The Psychology of Human Society* in 1926, Ross's student Charles A. Ellwood extrapolated Ross's theory of social control. For Ellwood, self-control was the penultimate form of social control because he felt it more likely to be successful than other externally applied and likely punitive forms. However, Ellwood appeared to lack faith in humanity's natural capacity for self-control because he firmly believed it was the work of schools to train pupils for social life and thus gain order in a potentially chaotic social world.

By the time Ellwood published his theories in 1926, educators such as Franklin Bobbitt had applied the science of efficiency to ordering of young people in society through the auspices of curriculum. Although Bobbitt was not the only social efficiency theorist, he became the most visible and widely read after publishing *The Curriculum* in 1918 and *How to Make a Curriculum* in 1924. Social efficiency models employed methods of task analysis to determine what skills students would need to become productive members of society and the workforce. Bobbitt's plan in particular prescribed general studies for all students until they proved capable of choosing and pursuing occupational training. "Extras," as Bobbitt calls them, should only be offered to those pupils of high ability, whereas pupils of low ability were to be offered abbreviated versions of the general studies. Thus, in effect, social efficiency curricula created a tracking system in which pupils' available educational outcomes were predetermined by the curricula they were offered.

As early as 1922, George S. Counts began to criticize the social efficiency curriculum in U.S. schools, claiming that they primarily served the wealthy at the wider public's expense. A later study he conducted of school boards found that schools best served the wealthy and were, in effect, under their control. This led Counts to accuse schools of working to maintain the existing socioeconomic stratification and to call for reform. Schools, Counts maintained, existed to prepare citizens capable of anticipating and shaping the future not to mirror and serve the factories while merely

reproducing the status quo. Although Counts's criticism focused primarily on issues of class, social stratification permeated society through the constructions of gender and race as well. In 1933, the powerful work *The Miseducation of the Negro* by Carter G. Woodson brought critically needed new perspectives—rooted in the lived experience of race in the United States—in how education can induce oppressed peoples to participate in the systems of domination that hold them down.

The time after the world wars brought a merging of curricular ideas that combined social control theories (also called social behaviorist) with more child-centered views generating what would be called “life-adjustment” or “life-needs” curriculum. New calls for traditional components to the curriculum (i.e., the 3 Rs and cultural heritage) continued and gained new strength. Ralph Tyler and what became known as the Tyler Rationale offered a systematic process to curriculum development in 1949, although criticisms soon followed. Rightly or wrongly, critics suggested that the Tyler Rationale was yet another attempt at limiting the curriculum and reproducing the social order.

Thus, U.S. schools appeared to be doing little more than enacting a plethora of curricular variations rooted in the ideology of social efficiency. Those who began to accept this phenomenon as fact then turned their attention to the question of how social control theory manifested itself in school practices and outcomes. Philip Jackson's 1968 and 1970 work, which expounded the concept of the hidden curriculum, proved fundamental to answering this question. The theory of a hidden curriculum provided an explanatory framework for analyzing the unintended results of schooling through making visible the unrecognized and sometimes unintended knowledge, values, and beliefs that are privileged through school practices. Additional criticism of the ways in which schools served as centers of social control soon followed.

The volatile political atmosphere of the 1960s and 1970s set the stage for the reconceptualization of the curriculum field, and criticism of schools' tendency to reproduce social stratification would again emerge during this time shedding new light on old problems and giving rise to three major strands of criticism: socioeconomic stratification, critical theories of race, and

feminist forms of analysis. Criticism began with a return to Counts's critique of the ways in which schools reproduce class structures when, in 1976, *Schooling in Capitalist America: Educational Reform and the Contradictions of Economic Life* by economists Samuel Bowles and Herbert Gintis examined the ways in which the hierarchy of schools mirrored the hierarchy of society. Both Michael Apple and Henry Giroux extended this concept claiming that schools function to literally reproduce existing class structures by basing curriculum on White, middle-class values and norms. In a further extension of what became known as reproduction theory, Apple and scholars that build on his work posited the ways in which schools maintain class, race, and gender stratification.

Issues of race and racial equality plagued U.S. public schools from the moment of their inception. In fact, social control theory's development and application to curriculum were in fundamental ways reactions to racial tensions. This is evidenced in Ross's, Ellwood's, and their contemporaries' fear that the new immigrants from Eastern and Southern Europe were genetically inferior savages who posed a serious threat to the maintenance of U.S. society. However, schools served racist purposes in much more visible ways through the exclusion of African Americans and subsequent practices of segregation. Although their philosophies varied greatly and at times conflicted, Booker T. Washington, W. E. B. Du Bois, Carter G. Woodson, Marcus Garvey, Malcolm X, and others all identified and decried the inequalities African Americans suffered at the hands of inequitable educational opportunities that worked to systematically oppress people of color. Even after desegregation connected with the 1954 *Brown v. the Board of Education* decision, however, issues of race in schools were considered a by-product of social ills rather than a distinct curricular problem. Thus, the move in the 1970s to examine race as an autonomous educational issue opened the doors to exploring the ways in which schools reify racial stereotypes and prejudice and work to oppress or marginalize ethnic minorities.

Although some may mark the 1970s as the birth of the feminist movement, its roots can be traced to the first half of the 19th century and advocates such as Judith Sargent Murray, Emma

Willard, Mary Lyon, Catherine Beecher, and Benjamin Rush who fought for the establishment of girls' schools that would emphasize and offer academic training. They were joined in the last half of the same century by activists such as Catherine Dall, Susan B. Anthony, Elizabeth Cady Stanton, and Louisa May Alcott who furthered the fight for educational equality through the call for coeducation. In their opinion, coeducation eliminated the inequality inherent in separate education and would lead to the same posteducational opportunities for both men and women. Although coeducation became a fact in public schools throughout the United States, equality in education remained illusive as the introduction of school sports, home economics, industrial arts, and the characteristic tracking inherent to social efficiency models sharply delineated boys' and girls' roles within schools. Some of the 1970s critiques targeted surface practices such as these along with sexism and gender stereotyping in textbooks, school norms and rules, and classroom practices. Other critics such as Madeleine Grumet and Janet Miller examined the embedded ways in which gender roles and hierarchies of gendered power were reproduced through schools and thus maintained in the larger realms of society and the workplace.

Meanwhile, a hemisphere away, Brazilian Paulo Freire, who became an international voice in the criticism of power structures within schools and society, penned *Pedagogy of the Oppressed* in which he outlined the ways that those with power work to dehumanize the powerless and what part education might play in the solution. The emergence during the last 30 years of advocacy and social justice pedagogy evidence both an awareness of and combatant to social control theory's presence in the curriculum. Yet issues of what knowledge is of most worth and who retains the privilege of making such decisions plagues an education system gridlocked in the rampant escalation and hegemony of standardization.

### Contemporary Thinking and Educational Research

Contemporary thinking in curriculum studies acknowledges the inherently political nature of all curriculum work—nothing is neutral. However,

debates remain about the extent to which biases and limiting social structures can be worked around in the pursuit of a more equitable curriculum. What Herbert Kliebard so aptly called the *Struggle for the American Curriculum* undoubtedly still proves to be the case.

## SOCIAL EFFICIENCY TRADITION

---

Social efficiency defies a single definition, but the idea that a good curriculum should result in a harmonious, well-functioning, and balanced society is a theme found in the work of all writers who used the term *social efficiency*.

The phrase was popular during the first few decades of the 20th century. It was used by many educators and educational reformers who were trying to identify an overall purpose for U.S. education. Because it was so popular, social efficiency meant different things to different people during the heyday of its use during the 1910s and 1920s. Similar to such terms as *accountability*, *effectiveness*, and *excellence* today, educational reformers and political figures could use the phrase *social efficiency* to appeal to audiences that had markedly different ideas in mind for the purpose of U.S. education. Critics found it quite difficult to argue

against efficiency—and indeed social efficiency—as the ultimate end of U.S. education.

There were three main uses of social efficiency during the first few decades of the 20th century, all of which should be acknowledged as part of the social efficiency tradition. One conception of social efficiency can be identified with the work of William C. Bagley, a second can be tied to the figure of John Dewey, and the third grows out of the efforts of David Snedden and John Franklin Bobbitt.

When educational philosopher Bagley used the phrase *social efficiency* in his book *The Educative Process* in 1905, he argued that the purpose of U.S. education was liberal education for all. The key to achieving this goal, argued Bagley, was high-quality teacher education. Drawing on the moral philosophy of Aristotle, Bagley used social efficiency as part of his overall argument for moral education. He wanted schools to teach students to suppress their individual wants, needs, and desires to serve their communities as strong, civic-minded citizens. Bagley used social efficiency during the early 1900s, but stopped using it by 1915 because he disagreed with the way that other writers, specifically Dewey and Snedden, had begun to use it.

Beginning about 1915 and most prominently in his 1916 book *Democracy and Education*, Dewey used social efficiency to argue for a state of society in which individual and communal goals were not in conflict with one another, but rather were in harmony. Dewey was concerned about the extreme position that individuals should subordinate their personal wants to the goals of the community, but he was equally concerned about the opposite extreme in which individual desires become so powerful that they overtake community goals. Especially in *Democracy and Education*, Dewey contends that a socially efficient society is one in which individual and communal goods are balanced so that society exists in a state of harmony, or equilibrium. Provided that the term was used to mean this balancing of individual and social goals, Dewey was an advocate of social efficiency, a point that is often forgotten in works on curriculum history.

A third use of social efficiency is found in the writings of Snedden and Bobbitt. Snedden, a sociologist, began to incorporate social efficiency into his sociology books and articles during the early to

mid-1920s. In keeping with his larger advocacy for vocational training, Snedden's social efficiency emphasized occupational training, close connections between schools and the economic ends of the state, and the creation of curriculum that trains students efficiently for jobs. The purpose of U.S. education, to Snedden, was vocational training, a position diametrically opposed to Bagley's. Snedden asserts that the proper place to begin when developing curriculum is by looking at the needs and desires of corporations. Once the needs of corporations have been identified, school leaders should develop curriculum that trains students to meet these needs as efficiently as possible, for students as well as for their future employers. Snedden served as a major advocate of the Smith-Hughes Act, which was passed by the U.S. Congress in 1917. The act expanded vocational training throughout the United States and promulgated precisely the kind of curriculum that Snedden wanted.

Some curriculum historians identify Bobbitt with an approach to curriculum known as social efficiency. Bobbitt's views were in many respects similar to Snedden's, although he was less concerned than Snedden was about the social ends of schooling. Bobbitt did not ignore the civic ends of schooling, but he argued powerfully that curriculum should be tied to economic production and the needs of industry. Bobbitt's 1918 book, *The Curriculum*, is often cited as a work that embodies a tradition of social efficiency, despite the fact that Bobbitt does not use the phrase even once in the book. In *The Curriculum*, Bobbitt argued for occupational efficiency, not social efficiency, a distinction that allowed him to keep curriculum development closely tied to training for occupations. The idea of social efficiency was too vague, indefinite, and idealistic to Bobbitt, so he never used it in any of his publications. Nevertheless, Bobbitt continues to be identified as a social efficiency educator by many writers in the field of curriculum history.

All three of these conceptions of social efficiency were prevalent throughout the first half of the 20th century. As a result, all of them are part of the social efficiency tradition in U.S. curriculum. Even though the term *efficiency* is not as popular as it was in the early 20th century, the three traditions are almost always found, when the purpose of U.S. education is discussed, typically with terms such as

*excellence, effectiveness, and accountability* as opposed to *efficiency*.

## SOCIAL JUSTICE

---

Social justice is about a fairer, more just distribution of social wealth and power; it is as well about full human recognition and the disruption of the structures of nonrecognition or disrespect or marginalization. Its goals are equity and democracy, awareness, social literacy, agency, engagement, and activism. Teaching for social justice might be thought of as a kind of popular education—of, by, and for the people—something that lies at the heart of education in a democracy, education toward a more vital, more muscular democratic society. It can propel us toward action, away from complacency, reminding us as well of the powerful commitment, persistence, bravery, and triumphs of our justice-seeking forebears—women and men who sought to build a world that worked for all human beings. Abolitionists, suffragettes, labor organizers, civil rights and peace activists: without them, liberty would today be slighter, poorer, more anemic—a democracy of form and symbol over substance.

Jean-Jacques Rousseau argued that in regard to justice, equality must not be understood to mean that degrees of power and wealth should be exactly the same, but only that with respect to *power*, equality renders it incapable of all violence and only exerted in the interest of a freely

developed and participatory law, and that with respect to *wealth*, no citizen should be so opulent that he can buy another, and none so poor that he is constrained to sell himself. The quest for social justice over many centuries is worked out in the open spaces and the concrete struggles of that ideal. Nothing is settled once and for all, but a different kind of question presents itself: Who should be included? What binds us together? What is fair and unfair? And always, the enduring questions in education: Education for what? Education for whom? Education toward what kind of social order?

If society cannot be changed under any circumstances, if there is nothing to be done, not even small and humble gestures toward something better, our sense of agency shrinks, our choices diminish. But if a fairer and more just social order is both desirable and possible, if some of us can join one another to imagine and build a participatory movement for justice, a public space for the enactment of democratic dreams, our field begins to open. We would still need to find ways to stir ourselves from passivity, cynicism, and despair; to reach beyond the superficial barriers that wall us off from one another; to resist the flattening effects of consumerism and the mystifying power of the familiar social evils such as racism, sexism, and homophobia; to shake off the anesthetizing impact of most classrooms and of the authoritative, official voices that dominate the airwaves and the media; and to, as Maxine Greene says, release our imaginations in order to act upon what the known demands, linking our conduct firmly to our consciousness. We would be moving, then, without guarantees, but with purpose and hope.

Teaching for social justice begins with the idea that every human being is of equal and incalculable value, entitled to decent standards of freedom and justice, and that any violation of those standards must be acknowledged, testified to, and fought against. The challenge is to find the capacity to oppose injustice, to stand up on behalf of the disadvantaged in a time when power is so consolidated and unfairly weighted against them. A guide and ideal is knowledge, enlightenment, and truth on one hand, and on the other, human freedom, emancipation, liberation for all, with an emphasis on the dispossessed. This is the core of justice, democracy, and humanism, unachievable in any

final form, but nonetheless a standard and a focus for energies and efforts.

Education is an arena of struggle as well as hope—struggle because it stirs in us the need to look at the world anew, to question what we have created, to wonder what is worthwhile for human beings to know and experience—and hope because we gesture toward the future, toward the impending, toward the come of the new. Education is where we ask how we might engage, enlarge, and change our lives, and it is, then, where we confront our dreams and fight out notions of the good life, where we try to comprehend, apprehend, or possibly even change the world. Education is contested space, a natural site of conflict—sometimes restrained, other times in full eruption—over questions of justice.

There is a long tradition of teaching whose purpose is to promote a more balanced, fair, and equitable order, to combat silence, defeat erasure and invisibility, resist harm and redress grievances. Several questions can act as guideposts for this kind of teaching:

- What are the issues that marginalized or disadvantaged people speak of with excitement, anger, fear, or hope?
- How can I enter a dialogue in which I will learn from students about the problems and obstacles they face?
- What experiences do students already have that can point the way toward solutions?
- What narrative is missing from the “official story” that will make the problems my students encounter more understandable?
- What current or proposed policies serve the privilege or the powerful, and how are they made to appear normal and inevitable?
- How can the public space—in my classroom, in the larger community—be used for discussion, problem-posing, and problem-solving and where fuller and wider participation is expanded?

Of course there are others, but these kinds of questions point a direction: We are, each of us, living in history, and we are subjects *in*, not objects *of*, history; what we do or don't do makes a difference; each of us is a work-in-progress, trudging forward, in-process, unfinished. And in a world as out of balance as this one, each of us has work to

do. Teaching for social justice is always more possibility than accomplishment involving as it does themes of democracy, activism, self-awareness, imagination, the opening of public spaces, and a robust engagement with a living history.

## SOCIAL MELIORISTS TRADITION

---

*Social meliorism* refers to a tradition in curriculum studies introduced and defined by Herbert Kliebard in his 1986 landmark publication, *The Struggle for the American Curriculum*. Kliebard describes four distinct interest groups of educational reformers from the late 19th to mid-20th centuries that were seeking to resolve the then-most basic dilemma of curriculum design and development: “what knowledge is of most worth.” These four groups were determining the purposes of education and were struggling for control of the curriculum in U.S. schools. Kliebard’s categories include (1) social meliorism where the schools were seen as a force for social change and the curriculum offered opportunity to forge a new vision for society, (2) humanism that had established a basic organizational structure for U.S. education and defined Western European thought as the most appropriate content for the school curriculum, (3) developmentalism where the selection of the curriculum was decided by psychological patterns and developmental stages of the student, and (4) social efficiency where the curriculum and administrative practices of schools were determined by a conception of efficiency and usefulness for the student. Kliebard stated that no single

group gained complete control of the curriculum, and his conceptual schema seems not intended to provide rigid distinctions to separate and classify educators but, instead, to allow the contemporary scholar of curriculum studies to envision tensions among the differing curricular perspectives from the past.

Kliebard portrayed the social meliorists through the work of sociologist Lester Frank Ward and 1930s educators from the field of educational foundations and curriculum—George Counts, Harold Rugg—who in other classifications of educational philosophies are typically deemed as social reconstructionists. Social meliorism embodied a social-economic critique of U.S. society and social conditions and viewed the curriculum and schools as a way to reform communities. Implicit in the standard definition of the term *meliorism* is the fundamental belief that a situation will improve. An interesting aspect of use of the term *social meliorism* in the field of curriculum studies pertains to whether those identified within this grouping maintained this basic faith.

Kliebard's groupings provide a metaconfiguration from which the many individuals aligned within the field of curriculum studies and the traditional educational philosophical orientations (the "isms" of perennialism, essentialism, progressivism, reconstructionism) could be seen in new ways, separating perspectives when necessary and underscoring commonalities and the "hybridization of the curriculum." Kliebard further brings a sophisticated conception of grouping and classification with the treatment of John Dewey, who he sees within all four of the humanist, developmentalist, social efficiency, and social meliorist traditions. Although many authors have defined and classified the field of curriculum studies and the field of education in relation to philosophical orientations and educational purposes, Kliebard provided an innovative and unique configuration with the term *social meliorism* becoming one of the most emblematic terms in the area of curriculum history and a signature concept of his career.

## SOCIAL RECONSTRUCTIONISM

---

Social reconstructionism, a movement in curriculum thought that first emerged in the late 1920s, aspired to redirect school curricula to consideration of significant social, political, and economic problems and offer solutions that promoted democratic social planning, and management. Largely associated with faculty members of Teachers College at Columbia University between the late 1920s and World War II, social reconstruction merged John Dewey's social philosophy and concept of scientific thinking with the notion of "cultural lag" and with various proposals for social democracy. Although social reconstruction is most often identified with the speeches and writings of George Counts in the 1930s, important alternative contributions were made by Harold Rugg and Jesse Newlon.

Social reconstruction combined Dewey's proposal that education is deliberative social inquiry into problems of collective importance with a socialist conviction that there are political solutions that can be projected and reasonably demonstrated in present trends, most particularly by technological progress and the expansion of democracy. Schools promote political and economic reform by engaging in democratic consideration of contemporary social problems. The conviction that there is a "cultural lag," a lapse between where science had brought society and what society promoted as its belief system, was articulated by W. F. Ogburn in *Social Change*, contending industrial growth and technology had taken humanity into a new social order. The dominant cultural orientation, in contrast, continued to reflect pretechnological and agrarian values. The excitement to close this cultural lag through social reconstruction resulted in a periodical, *The Social Frontier*, where options for the reform of society were considered.

Counts is recognized as a principal of social reconstruction through schooling. Although the social and economic crisis of the Great Depression

highlighted the urgency for new directions in social management, Counts's notions of schools as agencies for social reform first emerged in the late 1920s. Counts rejected child-centered progressive education for a curriculum that confronted contemporary political, economic, and social issues and probed structural solutions. His criticism of schooling based on learner interests served as the basis for a 1932 Progressive Education Association conference presentation by Counts entitled, "Dare Progressive Education Be Progressive?" In his subsequent book, *Dare the School Build a New Social Order?* Counts contended two features of U.S. culture were the basis for the economic catastrophe of the Depression: Devotion to individualism over social cooperation and private control of technological innovation. He exhorted teachers to expand their political influence as a collective body by unionizing and to set a clear political agenda for change. Schools were to redirect the curriculum to the consideration of relevant contemporary social problems, indicating how private ownership of resources and competition stood in opposition to human progress, presenting solutions based on collective political action.

Counts contended it was the educator's role to determine what policies offered the surest path to economic and social betterment and promote these solutions in discussion of social problems. Although Counts was actively involved in the American Federation of Teachers and wrote throughout the 1930s on the need for reorientation of the economy to collective ownership of resources, Counts did not produce any specific curriculum plan for social reconstruction. His decision to not support a local union action in the late 1930s brought him to question his personal commitment to economic democracy; his later writings shifted from the social concerns dominant in his writing in the 1930s.

In contrast to Counts, Rugg offered a resource designed to invite students to direct consideration of contemporary social problems and instructional guidance. Unlike Counts, Rugg supported child-centered educators and advancement of the individual. Rugg argued that in democracy both individual rights and social needs are promoted. Teachers were to model and teach tolerant understanding and critical questioning. Education served students as "sovereign personalities," assisting in

awakening individual potential and highlighting that individual interests are inextricably joined to the interests of the social collective. Rugg called for application of "the sustained yield principle," a conservation of resources to ensure that all may flourish and that social and natural resources can be both used for social and personal benefit, replenished through thoughtful conservation.

Rugg's personal contribution to the school curriculum, a series of social studies pamphlets that evolved into the text series, *Man and His Changing Society*, affirmed the operating principles that guide Rugg's aims of education, a tolerant understanding and a critical questioning of social standards. Rugg's texts invited young people to question U.S. policies and came under attack by the American Legion as unpatriotic. Rugg and later Counts were subject to investigation by the Federal Bureau of Investigation for possible communist affiliation.

Before coming to Teachers College, Newlon gained recognition as superintendent of schools for Denver, Colorado, for implementing an experiential curriculum and instructional innovations. Newlon promoted the efforts to realize the greater welfare of people through democratic deliberation using the scientific act of thought as developed by Dewey. Social deliberation was enacted in what Newlon labeled a "functional curriculum," a core study of social problems using the past as resource for resolution of pressing social difficulties. Cooperation is the standard for teachers and students. The elementary school focus is on basic skills in this cooperative environment with secondary schools focusing directly on social problems and offering electives to students to pursue individual interests. Among approaches Newlon proposed to open democracy to all people were (1) socialization of principal utilities and key industries that are failing financially, (2) the formation of cooperatives, (3) federal ownership of all mineral rights, (4) extension of worker rights, and (5) a new political alliance of progressives, socialists, and liberals for further redress of the limiting of democracy.

## SOCIAL STUDIES EDUCATION

---

Although educators disagree about the nature and the content of the social studies, such disputes are limited in the United States for two important reasons. The first is that the National Council for the Social Studies (NCSS) exerts a dominant influence on the way elementary and secondary schools teach the social studies and on the training that colleges of education impart to prospective teachers of the social studies. The second is that the NCSS seeks to ensure that practitioners meet standards most professionals accept as appropriate. Although NCSS maintains standards, it includes within the organization scholars who express a range of opinions. At regular intervals, these scholars meet, revise the standards, and change their recommendations for teaching to accommodate developments in the field. Because the NCSS acts as a legitimate professional group in a democratic society, it ensures the continual evolution of ideas about the nature and the content of the social studies.

The NCSS defines the field as an integrated study of the social sciences that enables young people to develop civic competence. Drawing on a range of disciplines such as anthropology, economics, geography, history, and political science, the social studies encourages students to make informed, reasoned decisions for the public good. The NCSS members hope that this ability to think reasonably about society will enable young people to function as citizens in a culturally diverse, democratic society within an interdependent world.

### Social Studies Versus Historical Studies

Although the National Education Association's Committee on the Social Studies used a similar definition to create the field in 1918, critics have

complained that the effect is to reduce the importance of historical studies and to replace it with mindless activities. For example, in 1987, conservative historians focused on a commission report sponsored by the Lynde and Harry Bradley Foundation to explore the conditions that would contribute to the effective teaching of history and to make recommendations on the role history should play in the curriculum. Named the Bradley Commission, the group included former presidents of all major professional associations in history, winners of prestigious prizes for writing and scholarship, and classroom teachers.

Complaining that 15% of the high school students in the United States did not take any U.S. history courses and nearly half did not enroll in courses in either world history or Western civilization, the Bradley Commission noted in 1987 that during the previous 5 years, several commissions had asked teachers to devote more classroom time to the central academic core of the curriculum. The Bradley Commission members believed that the discipline of history deserved more concentrated attention because it enabled students to understand change and to recognize the continuities between eras in the past and the present time, enhanced personal growth among the students by offering a sense of identity, and encouraged intelligent citizenship by providing different examples of virtue, courage, and wisdom. The answer the commission report offered was for teachers to cover six themes important to historians: cultural diffusion; human interaction and the environment; values, beliefs, and institutions; conflict and cooperation; comparisons of developments such as feudalism or slavery; and patterns of social and political interaction.

Supporters of the Bradley Commission claimed that the report encouraged teachers to shift from the social studies approach and focus the entire curriculum on historical studies; however, this was only partially true. Actually, the NCSS adopted the idea of arranging the curriculum around themes instead of textbooks or specific topics in 1992. In addition, the themes the NCSS adopted were similar to those that the Bradley Commission proposed.

The 10 themes that appear in the NCSS standards seek to integrate the various subject matter fields into the social studies by providing a framework for instruction. The themes include a study

of the concept of culture, an exploration of the ways that cultures change over time while retaining continuity with their past forms, and an understanding of how the environment influences the ways that people learn and grow. In an effort to open the students to wider ideas, the themes move to studies of how people live within different institutions, analyses of power and authority, and considerations of how people can participate in community, national, and global affairs.

### Classroom Instruction

Rather than having teachers concentrate on traditional textbook lessons that follow those themes, the NCSS recommends that social studies teachers attend to five qualities for effective instruction. First, the lessons should be appropriate to the maturity and the concerns of the students. This means that the lessons should relate to the students' lives. Second, the information within social studies lessons should come from a wide range of knowledge about the human experience. Third, social studies lessons have to involve ethical considerations. Fourth, the lessons must challenge the students' thinking, expose them to conflicting views of various topics, and encourage them to make intelligent evaluations. Finally, the students must engage in activities to accomplish some end that interests them rather than passively absorb information.

To demonstrate how teachers could develop such lessons, the NCSS offers several sample curriculums. For example, NCSS joined with the Mountain Institute to create a curriculum entitled *Mountains: A Global Resource*. Funded by a grant from the U.S. Agency for International Development, this curriculum contains four extended lessons that would take about a year to complete. A description of the first lesson illustrates the ways the NCSS wants curriculums to unfold.

The topic of lesson one is the importance of mountains. Scheduled to take 2 or 3 days of class time plus homework, the students fulfill five themes of geography. To understand location, the students find where mountain ranges appear in relation to each other and to the students' homes. To determine variations among places, the students describe an area and the culture of the people living there. To recognize how human beings

respond to their environments, the students consider how people adapted to their surroundings as well as how they changed the environment to survive. The students explore the ways people spread ideas and materials around the world to improve their lives. Finally, the students recognize the nature of a geographic region as an area that is unified in some way and gives identity to the people living in the region.

The project, *Mountains*, suggests activities for students that capture their interests and that integrate the five themes from geography listed earlier. One such assignment is to make an informational brochure illustrating the natural and cultural resources found in an area. The lesson begins with the teacher dividing the class into teams of three people. To each group, the teacher designates a specific mountain range and the team members begin their research. When the teams finish their work, they demonstrate their brochures to the class.

### Social Issues

It is important to realize that the NCSS recognizes more than the concerns of subject matter specialists. The members are sensitive to social conditions as well. For example, during the 1960s and 1970s, as school districts engaged in racial desegregation, teachers introduced courses in Black studies or Black history. Although this innovation satisfied critics who complained that social studies neglected the activities of African Americans, educators noted that such courses implied that there were only two groups in the United States, Blacks and Whites. As a result, educators, such as James Banks, offered teaching strategies for what they called ethnic studies. Holding up the idea of the melting pot as an unrealized myth, Banks asserted that ethnic groups were intensifying efforts to glorify their pasts and develop pride among the members. As a result, Banks called on teachers to help children understand how the many different groups in U.S. society interacted to teach the children to be tolerant. Such lessons, he argued, would benefit all children whether they belonged to a minority group or not.

Adopting a view similar to Banks's, the NCSS advocates multicultural education to combat the cultural blindness caused by racism and sexism.

The organization calls on educators to respect ethnic diversity, to encourage participation of diverse peoples, and to facilitate change in the direction of increased openness in society. In addition to adopting curriculums that portray the heritages and interests of various groups, the NCSS urges schools to create environments consistent with ideals of diversity and. According the NCSS, this mandate for multicultural education requires that teachers and administrators undergo continuing staff development programs ensuring they appreciate cultural pluralism and have the skills to create a positive multicultural environment for the students.

Although social studies and multicultural education may begin with lessons about local or national issues, the NCSS recommends that the instruction move toward global and international education wherein students gain knowledge and appreciation of world cultures, recognize the nature of cultural differences, and develop attitudes of tolerance and empathy. The hope is that students may begin with the study of a specific problem such as population change in a particular area; however, they would explore how those changes in one place led to alterations in other places as well. In this way, the students might learn about the interrelated nature of events and, thereby, prepare for their roles as participants in a global and interdependent society.

### Advocacy

Because the NCSS functions as an interest group within a democratic society, the organization argues that the integrity of the social studies depends on the influence of legislative bodies. For example, in 2002, the U.S. Congress included a definition of the social studies in its implementation of the legislation called No Child Left Behind (NCLB), but the congressional representatives did not require assessments of the social studies classes as they did for reading and mathematics. Although the NCLB required state departments of education to ensure that highly qualified teachers conduct the classes of civics, government, economics, history geography, and history that constituted the social studies, the absence of regular assessments meant that many school districts spent less class time on this area of study than on other areas that the NCLB did measure, such as mathematics and language arts.

To offset the problems caused by NCLB and to ensure that local schools adopt carefully designed and appropriate social studies programs, the NCSS engages in extensive advocacy campaigns, joins other educational groups in lobbying for appropriate legislation, and establishes local organizations to influence local, state, and federal representatives. Calling this approach positive advocacy, the NCSS seeks to show everyone that the social studies can create effective citizens.

As part of the advocacy campaigns, the NCSS serves as one of the specialty program associations for the National Council for Accreditation of Teacher Education (NCATE). This means that NCSS prepares evaluators who visit the schools and colleges of education preparing teachers for elementary and secondary schools to ensure that those programs met NCSS standards. In general, these standards relate to subject matter content that teachers must know. Although the NCSS standards for social studies teacher preparation assess the extent programs offer instruction on teaching methods, this section of the NCSS standards follows the widely accepted standards for beginning teacher licensure promulgated by the Interstate New Teacher Assessment and Support Consortium. Nonetheless, with its prominence in NCATE, the NCSS can require that only programs of teacher conforming to its model receive accreditation. Such approval can be important because many state departments of education require that programs preparing teachers for licensure maintain accreditation from agencies such as NCATE.

### Other Agencies Offering Training in Citizenship

Although the NCSS encourages the orderly evolution of the social studies, the changes come slowly because of the delays inherent in most democratic processes. At the same time, agencies other than schools offer training in citizenship. For example, social settlements, such as Hull House in Chicago, sought to bridge the gaps among the citizens in the newly developed urban centers during the 1890s. During the civil rights movement, African American leaders established what they called Freedom Schools throughout the South to enable African Americans to exercise their rights as free and equal citizens. Educators and sociologists may designate

these extracurricular efforts as social education to distinguish them from the lessons that take place in schools under the title of social studies.

The important point to realize is that social education often works itself into social studies education. This is the case with both examples listed. Under the auspices of John Dewey and other progressives, educators accepted the idea of the school as a social center with the result that many social studies lessons provide activities that show the students how the different groups within any city depend on each other. In addition, the aims and the activities of the Freedom Schools appear in the mandates for multicultural education that the NCSS adopted.

### Final Thoughts

Although the social studies are contested areas, the members of the NCSS seek to select the important ideas within these controversies in ways that advance the ideals of democracy. This comes about through the recommendations of what the social studies are, suggestions for the instructional methods teachers should use, and by the ways the organization follows democratic procedures of change and reform.

## SOCIAL STUDIES EDUCATION, HISTORY OF

---

The reports of the National Education Association's (NEA) Commission on the Reorganization of Secondary Schools (CRSE) called for the social studies as an integrated area of study in secondary schools in 1916. As part of that commission, the NEA had created a separate Committee on the Social Studies whose members defined the area as comprising subjects with content related to the development of human society. Examples of such subjects included history, geography, economics, and political science. According to this report, the aim of the social studies was to cultivate good citizenship. Although the members of the committee wanted students to develop loyalty to their cities, their states, and to their nation, they hoped the students would temper such narrow patriotism with a sense of membership in a world community.

A similar set of ideas had appeared in 1893 when the Madison Conference described courses appropriate for high schools as part of the reports of the NEA's Committee of Ten. When the members of the Madison Conference considered how teachers should arrange the students' assignments, they recommended that teachers allow the students to study topics that interested them and challenged them to solve problems. These ideas reappeared in the reports of the American Historical Association's

(AHA) Committee of Seven that surveyed practices of secondary school history teachers in 1899, and in the AHA's Committee of Eight that released its report about teaching history in elementary schools in 1909.

The similarities among these reports about school studies derived from the fact that areas of professional study such as history underwent significant changes. For example, James Harvey Robinson called for a new history that encouraged readers to learn about the ways the world changed. Robinson complained that historians tended to compile accurate but mind-numbing lists of names of minor royal figures, dates of insignificant battles, and details of peace treaties. To bring life to the study of history, Robinson urged historians to include the work of anthropologists, novelists, economists, and sociologists in ways that would help readers understand the development of present conditions. These ideas and those of Robinson's like-minded colleagues, such as Albert Bushnell Hart, appeared in the report of the Committee of Ten because Robinson attended the Madison Conference and his ideas of the new history dominated the 1916 report of the Committee on the Social Studies.

Despite the NEA's pleas for social studies to be socially relevant, Harold Rugg complained in 1923 that schools remained tied to history texts. Students memorized lists of battles, dates of the coronations of kings, and details of legislative processes. Thinking that a reasonable alternative was some sort of unified social studies, Rugg developed a series of textbooks based on explanations of social problems. To write these textbooks, Rugg drew information from a wide range of social sciences, arranged it in order of increasing complexity, and applied it to analyses of different significant issues. In this way, he wrote eight books that elementary school-age children could understand and six books designed for secondary school students. Rugg's ideas were not new. He took the idea of research topics from the Madison Conference, turned the topics into social problems, and organized the social studies program around them.

Although Rugg's textbooks enjoyed initial success, historians, such as Charles Beard, turned against Rugg's model by the advent of the Great Depression. Writing for the AHA's Commission on the Social Studies in 1932, Beard complained

that exploring present-day problems did not prepare children to become intelligent citizens. Society changed constantly. There was no way to predict the conditions that would arise. No one knew which problems would persist, and which issues would disappear. Thus, Beard called for textbooks that enabled the students to develop appropriate ideas, maintain courage, and enhance their imaginations.

However, Beard could not suggest how social studies should help students develop what he called many-sided personalities. A solution came from Beard's colleague on the AHA Commission on the Social Studies, Leon Marshall, who suggested that social studies courses concentrate on processes all societies share. Marshall and his daughter, Rachael Marshall Goetz, claimed that every society must contend with continuing biologically, guiding human motivation, and molding personality. If students learned how different societies coped with these difficulties, they would develop the critical thinking skills to act intelligently when new problems arose in society.

To advance these ideas, in 1934, the AHA assumed responsibility for editing the magazine, *The Social Studies*, for teachers of history, social studies, and social sciences. This became the journal for the National Council for the Social Studies (NCSS) that had been founded in 1921. The AHA relinquished its responsibility for editing *The Social Studies* in 1937, and the NCSS established the journal, *Social Education*, aimed at junior high school and high school teachers, as its official journal.

The social studies received further endorsement in 1936 when the College Entrance Examination Board (CEEB) made it possible for students to study history in a manner consistent with the social studies. The CEEB commission defined history as the study of human beings in society from their beginnings to the present day and added that the study should be undertaken in as broad a manner as possible. When the members of the CEEB commission described the methods of teaching these history courses, they recommended organizing the information in the ways that Marshall and Goetz had done. Today, the NCSS preserves Marshall's idea by organizing the social studies around themes such as understanding how the environment influences people and how people live within different institutions.

As the social studies changed throughout the 20th century, the ideas that inspired the conception of the field remained constant. These included the need for relevance, the desire for students to engage in problem solving, and the effort to arrange social studies material in ways that would enable student to become good citizens. For example, in the 1970s, educators accused the social studies of being biased in favor of White, middle-class families. The remedy they suggested was to have students study various ethnic groups and view history through the eyes of minority peoples. By the 1990s, these calls turned into multicultural education.

Multicultural education extended Marshall's hope for students to learn about social processes and compare the ways many different societies coped with universal problems. The ideal of tolerance that multicultural education expressed had appeared in the 1916 report of the Committee on the Social Studies in the hope that students would temper narrow patriotism with a sense of membership in a worldwide community.

## SOCIETY FOR THE STUDY OF CURRICULUM HISTORY

---

The Society for the Study of Curriculum History (SSCH) was established in 1977 by a group of curriculum scholars meeting at Teachers College, Columbia University. The society's purpose was,

and continues to be, to encourage the scholarly study of curriculum history and provide an opportunity for the presentation and discussion of research inquiries into curriculum history. The society has met annually in conjunction with the American Educational Research Association since that time. Established scholars, emerging scholars, and doctoral students present papers of interest to the membership for discussion and feedback. Meetings often include keynote speeches or papers by leading curriculum and educational history researchers and symposia that foster collegial interchange. Papers presented at SSCH generally reflect interpretations of important issues and influential events and persons in the history of the curriculum field, and in the history of the formation of curriculum theory, curriculum policy, and curriculum practice. Although most papers have focused on practices in U.S. schools, many papers have been presented by international scholars on Australia, Japan, England, Germany, and Israel as well as on other European and Asian countries.

In 1989, 23 papers were published in the edited book. Since 1991, selected papers presented at the meetings have been published in journal format under the title of *Curriculum History*. Some papers presented at the meetings have been indexed in ERIC; others were published in an edited volume, *Explorations in Curriculum History*.

Many of the professors were, at the time of the organizational meeting, noted names in the field of curriculum, including some whose names are found in this encyclopedia. Among the other founding members who have provided guidance for scholars in the years since 1977, either through their writing or their chairing of doctoral committees, were Lawrence A. Cremin, O. L. Davis Jr., Arthur W. Foshay, Murry R. Nelson, A. Harry Passow, William H. Schubert, Daniel Tanner, and Laurel N. Tanner. In the years since its founding, the society has provided a place for emerging scholars to present their fledgling ideas and receive feedback on their work. Many of these scholars have gone on to faculty positions in noted universities in the United States and internationally.

## SPECIAL EDUCATION: CASE LAW

---

When parties disagree on an issue, one may choose to involve the court system to settle the disagreement by applying the law to the facts and rendering a decision. Numerous decisions rendered by our courts affect special education and the field of curriculum studies.

### *Board of Education of Hendrick Hudson Central School District v. Rowley*

*Rowley* (458 U.S. 176, 1982) was the first special education case decided by the U.S. Supreme Court. The case centered on Amy Rowley, a deaf student who was an excellent lip-reader. At the beginning of her first-grade year, as her individualized education program (IEP) was being developed, her parents insisted the school provide Amy with a qualified sign-language interpreter. The school administrators concluded that Amy did not need the services of an interpreter because she was achieving the learning outcomes of the curriculum and was socially integrated into the classroom. As a result, the request for an interpreter was denied. Amy's parents filed suit against the school district, claiming that the refusal of the school to provide an interpreter for their daughter denied her the "free appropriate public education" that is guaranteed by the federal government. The U.S. Supreme Court found that the evidence established that Amy received an appropriate education because she was easily progressing from grade to grade and the district did not have to provide her with a sign-language interpreter.

### *Irving Independent School District v. Amber Tatro*

Amber Tatro was an 8-year-old girl with spina bifida, resulting in a disorder that prevented her from emptying her bladder voluntarily. As a result, she needed frequent catheterization to empty her bladder and avoid damage to her kidneys. The catheterization procedure was fairly simple, and her parents, babysitter, and teenage brother were all qualified to perform it. Amber's parents sought to have school personnel perform the catheterization procedure, but were denied. Amber's parents filed suit against the school district claiming Amber's "free appropriate public education," which is guaranteed by the federal government in the Education of the Handicapped Act, was being denied. In particular, the suit claimed that the "related services" that Amber was entitled to receive as required by law included catheterization procedures. The case was heard by the U.S. Supreme Court [*Irving Independent School District v. Amber Tatro* (468 U.S. 883, 1984)], which ruled that providing the catheterization procedure was a "related service" and should be provided by the school district.

### *Honig v. Doe*

*Honig v. Doe* (484 U.S. 305, 1988) involved two students who were expelled by the San Francisco Unified School District for violent and disruptive behavior. It was argued that the behavior of the students was a result of their emotional disabilities and the students should, therefore, not be expelled. On appeal, the U.S. Supreme Court ruled that both students' behavior was causally connected to their disabilities. Because their behavior was a manifestation of their disabilities, expelling the students violated their rights guaranteed to them under the Individuals with Disabilities in Education Act. If a school is considering expelling a student with a disability, a manifestation determination review must be conducted to determine whether the student's behavior was causally related to his or her disability.

### *Cedar Rapids v. Garret F.*

Garret F. was a student paralyzed from the neck down and required numerous medical services

throughout the day. These services were necessary for Garret to remain in school during the day, so it was argued that under the Individuals with Disabilities in Education Act, the school district should provide these services to Garret. In *Cedar Rapids v. Garret F.* (526 U.S. 66, 1999), the U.S. Supreme Court ruled that the “related services” provision of the Individuals with Disabilities in Education Act required school districts to provide nursing services to a student with a disability during the school day if those services are required for the student to remain in the school. Until this ruling, not all medically associated services were provided by school districts to students with disabilities.

### *Schaffer v. Weast*

In *Schaffer v. Weast* (546 U. S. 49, 2005), the U.S. Supreme Court examined who has the burden of proof in due process hearings. This case arose from the educational services provided to Brian Schaffer, a student who suffered from learning disabilities and speech-language impairments. When dissatisfied with the educational placement of their son, Brian’s parents initiated a due process hearing challenging the Individualized Education Program developed by the school. The matter was heard by the U.S. Supreme Court, which noted that the Individuals with Disabilities in Education Act does not state which party bears the burden of proof in a due process hearing that challenges an Individualized Education Program. The Court ruled that the burden lies on the party seeking relief.

### *Winkelman v. Parma City School District*

When disagreement arose regarding the content of the individualized education program developed for Jacob Winkelman, a 6-year-old with autism spectrum disorder, Jacob’s parents sought relief by filing a request for due process, alleging that the school had failed to provide Jacob with a “free appropriate public education” as required under the Individuals with Disabilities in Education Act. Jacob’s parents proceeded without legal counsel, until the Court of Appeals ruled that parents are not authorized to appear without legal representation in asserting their child’s rights. The matter was then heard by the U.S. Supreme Court (*Winkelman v. Parma City School District* [530 U.S. 516,

2007]), which examined whether parents who are not licensed attorneys, acting either on their own or on behalf of their child, may proceed in court without legal representation. The Court ruled that because parents have legal rights under the Individuals with Disabilities in Education Act, parents may represent their children’s interests in special education cases and are not required to hire legal counsel.

## SPECIAL EDUCATION CURRICULUM

---

Special education curriculum encompasses specially designed instruction, as well as all educational and related services for students identified as having a disability according to federal and state regulations. Special education curriculum has evolved throughout the eras. Early curricular models and methods of instruction were based largely on medical, psychological, and behavioral orientations with an emphasis on remediation of a deficit or disorder. Contemporary special education curricular models are tied to provisions of the Individuals with Disabilities Education Act (IDEA), and influenced by reform movements in the fields of special (i.e., inclusive schools movement) and general education (i.e., multiculturalism).

This entry first discusses the regulations that govern special education curriculum, including the least restrictive environment (LRE) continuum and federally designated categories of disability. Next, the entry discusses classroom instruction

and management for special education curriculum. Lastly, this entry briefly addresses the future direction of special education curriculum.

### Regulations

Reauthorized IDEA 2004 has extensive regulations in all areas that govern special education curriculum. In essence, IDEA provides for free, appropriate public education, nondiscriminatory evaluation, individualized education, due process, and LRE. These provisions mean that students with disabilities are entitled to educational and related services at no cost to parents in public schools. No students can be excluded from public education because of a disability. To determine whether students are eligible to receive special education instruction or services, they must be evaluated using assessments that are not biased with regard to race, culture, or disability. Decisions regarding students cannot be based on one test. Rather students must be assessed by a multidisciplinary team in their native or primary language using relevant and appropriate instruments. In addition, parental consent to evaluation is not consent for possible special education placements.

Instruction must be individualized to meet specific needs. Required is an individualized education program (IEP) prepared annually. The IEP is the cornerstone of the curriculum and instruction provided to students with disabilities and has many tenets, the basics of which include the following: a brief description of the student's level of functioning, goals with short-term objectives on how to achieve those goals, identification of which school personnel are responsible for providing the instruction and related services for the student, specific allotment of time for all areas of instruction, and a plan for how progress will be assessed and goals achieved. Students with IEPs are either included in individual state standardized assessments or by an alternative assessment process. Students with disabilities are entitled to adaptations during assessment, such as, extended time. At least one general education teacher must participate as a member of a team that prepares the IEP, and the IEP must address how students will be included in general education programs. When appropriate, the student attends her or his IEP

meetings. Placements that are not in general education classrooms must be justified.

Through any stage, students with disabilities and their parents have due process rights. If there is a dispute regarding eligibility, instruction, or services, no changes can be made until the issues and concerns are resolved by an impartial hearing or a court if necessary. School personnel also have due process rights and can request an impartial hearing to resolve disagreements. Mediation must be made available early and the state bears the cost, not parents.

### *Least Restrictive Environment*

Typically, the LRE is the general education classroom with some kind of support for students with disabilities. The inclusive general education classroom (comprising students with and without disabilities), co-taught with one general education teacher and one special education teacher is considered by proponents of democratic classrooms and accessible instruction to be the ideal LRE. Or, the special education teacher (sometimes called resource teacher) is in the general education classroom part of the day or all day, but can either be a co-teacher or provide instruction separately within the classroom.

Moving on the LRE continuum from least to most restrictive environment is the "mainstream" general education classroom. Students with disabilities spend the majority of their time in this classroom taught by a general education teacher. Instruction and assessment are adapted or modified according to the IEP, and many students with disabilities are "pulled out" to receive individualized instruction (i.e., reading or learning disability specialist) or therapy (i.e., speech-language therapist, social worker, or counselor) one-on-one or in a small group.

Next on the continuum is the self-contained special education classroom. Students with disabilities spend all or part of their day in a classroom with a special education teacher who is expected to provide a highly individualized curriculum and unique instructional strategies to help students learn. Although self-contained, the classroom is not intended to be separate from the community of the school. Students with disabilities and their teachers are part of the school community,

and the goal is to return students to lesser restrictive environments. Students in a self-contained setting may spend part of the day in a general education classroom for one or more academic subjects or socialization, and may be pulled out to receive individualized instruction by another specialist.

When the needs of students with disabilities cannot be met in a public school because of lack of appropriate classrooms and programs, students may be eligible for a separate private or public school. For short-term crises or when longer-term severe problems exist (i.e., when students are unable to live at home) a residential facility is an option. These separate placements can be within the students' home area or out-of-state, all paid for by the school district. These more restrictive placements are therapeutic in nature with intensely individualized instructional strategies. A plan to return to a lesser restrictive environment must be in place. Finally, students with disabilities may be hospitalized for illness or surgery, or home for illness or recuperation and are entitled to services.

### *Federal Categories of Disability*

IDEA's federal categories of disability are as follows: specific learning disability, speech or language impairment, mental retardation, emotional disturbance, hearing impairments, deafness, visual impairments/blindness, deaf-blindness, orthopedic impairment, other health impairment, multiple disabilities, autism, and traumatic brain injury. To meet the needs of students who fall within these federal categories, the special education curriculum encompasses academic instruction and what is commonly referred to as related services, those supports that students with disabilities require to benefit from instruction. These related services include speech and language therapy, occupational and physical therapy, counseling (psychological, behavioral, social), and transportation.

IDEA does not require services for gifted and talented students. The federal definition of this group of students is described in Pub. L. No. 100-297, Gifted and Talented Students Education Act of 1988, and refers to students with advanced intellectual, academic, creative, specific academic or leadership ability, or in the performing and visual arts who require specialized instruction, services or

activities not ordinarily provided by the school. Curricular adaptations for gifted and talented include an accelerated model (skipping grades, advanced placement classes, honors programs), compacting or telescoping curriculum (learning in less time), subject matter enrichment, and placement in magnet schools. Other students not eligible to receive special education services are students with attention deficit hyperactivity disorder (ADHD) and those with poor academic abilities not associated with a specific disability.

### **Classroom Instruction and Management**

The literature and research on special education curriculum and the strategies for best practices in instruction, classroom organization, and management are vast. The special education curriculum comprises a multitude of teaching methods that are used in small and large group settings, as well as in individual instruction. A variety of learning strategies and mnemonic devices are employed to help students with receptive and expressive language abilities, reading, writing, math, and other subject areas. Related service professionals (learning disability teachers, reading teachers, speech-language therapists, occupational therapists, physical therapists, social workers, counselors) have their own specialized curriculum, with a unique set of diagnostic, instructional, and therapeutic approaches.

Curricular adaptations or modifications are ways in which general education teachers can support the needs of students with disabilities in their classrooms. These are modifications to lesson formats, instruction, classroom setting, homework assignments, grading, and assessment. Diagnostic teaching, curriculum-based assessment (CBA) and curriculum-based management (CBM) are models for teachers to determine what their students' abilities are so teachers can design instructional methods and adaptations that will assist learning and build on students' capabilities. Instructional adaptations may include teaching pre-skills, introducing new skills or content at individualized rates, providing multiple and varied opportunities for review and practice, and designing individualized study guides, and organizers.

Computer and assistive technologies have become an integral part of the special education

curriculum. With the Assistive Technology Act of 1998 (105–394, S.2432), the federal government defined assistive technology as “any item, piece of equipment, or product system, whether acquired commercially, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities.” Communication and visual aids, orthotics, wheelchairs and any adapted toys, and utensils are considered to be assistive technology, particularly for students with severe and multiple disabilities. Assistive technology enhances students’ ability to communicate and access the curriculum. For example, voice recognition equipment can convert the spoken word into the written word. Conversely, students who have difficulty communicating orally, can use various forms of augmentative communication (i.e., communication board with pictures or words) to express themselves.

Universal design for learning (UDL) is an approach that uses new technologies that provide direct or immediate access to learning for individuals with and without disabilities. Products and services are directly accessible and are independent of or interact with assistive technologies. Examples of products and services designed from the outset to accommodate a range of learning styles are captioned or narrated videos, speaking spell checkers and dialogue boxes, voice recognition, and picture menus. A universally designed curriculum is one designed initially to meet the needs of a diverse array of learners and learning styles, in contrast to a middle-of-the-road or one-size-fits-all curriculum that requires adaptations and modifications. The intent of a universally designed curriculum is to create full access for students with disabilities to the general education curriculum.

With regard to classroom management models for the general or special education teacher, the goal is to help students learn to develop autonomy and self-control when it comes to their own behavior. One is the cognitive behavior management (CBM) model, which teaches students self-monitoring and self-reinforcement skills. This is in contrast to a behavior management system that is based on maintaining external control through a system of rewards and consequences. The latter behavioral model may include a “token economy system,” which is a behavior management system in which students earn tokens in exchange for

rewards or privileges. Some curriculum uses a combination of behavior management models.

Other models are individualized and may include the psychoanalytic approach with a reliance on individual psychotherapy; the psycho-educational approach with an emphasis on meeting individual needs and use of projects and creative arts; the humanistic approach, which is nonauthoritarian, open, affective, and personal with the teacher as facilitator; the ecological approach, which involves all aspects of the student’s life (school, home, community) and an emphasis on educational and life skills; and the behavioral approach, which involves measurement and analysis of behaviors and emphasis on a system of rewards and consequences.

Peer tutoring or learning, peer buddies, and peer mediation are examples of how students can work with each other, as part of the special education curriculum. Peer curricular models provide opportunities for diverse students to tutor one another for different academic subjects, learn together in small groups, develop a friendship with another student to enhance social skills, assist in going to and from classes, or mediate disputes.

In curricular models of collaboration, consultation, partnerships, and interactive teaming, educators, professionals, and parents of students with disabilities work together to foster an environment for learning. The curriculum in school can be linked with students’ interests, knowledge, and experiences out of school, parents become more aware of the complex tasks of teachers, and all professionals involved in the special education curriculum can welcome different yet valuable ways each contributes to the educational process. Through active collaboration and sustained communication, parents, general and special education teachers, and specialists can nurture the self-esteem, self-discipline, literacy, communication, and social and cognitive abilities of students with disabilities.

Those who are proponents of inclusive classrooms and schools advocate for democratic classrooms, accessible instruction, and responsive curriculum for students with disabilities. They recommend going beyond the whole-class, uniform single-lesson format and incorporating inquiry-based, problem-solving, and constructivist approaches. In addition, they support flexible groupings of students, collaborative problem

solving, and values that foster appreciation and acceptance of students with cognitive, social, and cultural differences.

### Future Directions

Some educators believe that dual systems of general and special education persist side by side, separate and unequal, but others believe that full-inclusion goes too far for many students with disabilities. In examining the special education curriculum, fundamental curricular questions apply. Is the curriculum interesting and engaging to students? Are there multiple opportunities for students to express their interests, experiences, and choices? Who is the student and what are her or his needs, interests, experiences, strengths, and challenges? What are the multiple ways of learning, based on the strengths, and abilities students already have? Does the classroom environment accommodate different needs and a range of learning styles? Are students engaged in a discussion of goals and rules? Are the daily rhythms and ongoing expectations conducive to learning? Future inquiry will continue to focus on what equity and accessibility mean for students with disabilities and students who learn differently.

## SPECIAL EDUCATION CURRICULUM, HISTORY OF

---

Historically, special education curriculum can be viewed before landmark federal legislation—Public Law (Pub. L. No.) 94-142, the Education for All Handicapped Children Act passed in 1975—and after this public law was enacted. Influenced by the civil rights movement, and by the U.S. Supreme Court’s 1954 *Brown v. Board of Education* ruling that separate education is not equal, Pub. L. No. 94-142 provided that “special classes, separate schools, or other removal of handicapped children from the regular education environment occurs only when the nature or severity of the handicap is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily.” The term *least restrictive environment* (LRE) emerged from this legislation, meaning all students with disabilities must be educated in as normal an environment as possible. In addition to the provision of least restrictive environment, the 1975 legislation provided for free, appropriate public education for “handicapped” students ages 3 to 21, individualized education programs (IEPs), due process protections, and protection in evaluation procedures.

During the 1970s, the LRE was considered to be a separate special education classroom on a full-time basis for the majority of students with disabilities. The concept of *mainstreaming* emerged during this time, a term used for permitting students in special education classrooms to be mainstreamed into regular or general education settings for part of the day or week. Usually, students were mainstreamed for music, art, recess, or assemblies, and only for academic classes if students were deemed qualified to meet academic expectations with minimal assistance.

At the beginning of the 20th century when compulsory public education took place, children with severe physical or cognitive disabilities typically did not attend public school. Either they remained at home, lived in, or attended private facilities or lived in state institutions. During the early 1900s, special classes began to emerge for students who were not doing well academically. Most likely, these were children who today would be considered to have mild language, learning, or cognitive disabilities.

Special education before 1975 was influenced by the social efficiency movement, which used industrial models to create efficient schools. Through psychological assessments (regarded as scientific testing), Intelligent Quotient (IQ) scores were used to identify categories of disabilities (i.e., levels of mental retardation). Results of intelligence and related tests resulted in students who fell below what was considered normal being placed in separate, special classrooms and schools.

By the 1950s, special education classrooms were common in public schools. These were considered to be segregated programs, and minimally academic in nature and often focused on development of manual skills. In addition, there were separate and segregated public day schools for children whose physical or cognitive disabilities were considered moderate to severe. For example, there were separate schools for children with physical disabilities, such as cerebral palsy or spina bifida. Children with autism usually were placed in programs with students considered to have severe emotional or behavioral problems. Typically, children who were considered to have moderate to severe mental retardation were in their own separate programs. In addition, there were special day or residential schools for children who were blind or deaf.

In 1985, Madeleine Will, in her role as assistant secretary for the Office of Special Education and Rehabilitative Services in the U.S. Department of Education, assessed the effectiveness of special education 10 years after the passage of Pub. L. No. 94-142. In her seminal report, Will described a dual system of regular and special education. She indicated that the majority of students with disabilities were placed in self-contained categorical classrooms in special public schools far from their neighborhood school. If students with disabilities

attended their neighborhood public school, typically they spent much of their day in pullout and resource-room programs. In most cases, the curriculum in the separate, self-contained, and resource programs was watered-down rather than adapted to meet the educational needs of students. Special education teachers, students, and their parents were typically segregated from the community of the school, and the relationship between parents and school personnel was often adversarial.

In addition, Will cited problems with eligibility requirements. Some students were misdiagnosed, and therefore mislabeled to receive educational services. Other students who required help fell through the cracks because of different and often faulty criteria used by state and local school systems for identifying and classifying students for eligibility to receive special education services. For example, there was an overrepresentation of African American males in special education, particularly in the categories of mental retardation and behavior disorders, an underrepresentation of Latino students, and an overrepresentation of Caucasian children in learning disabilities.

Will's report and the work of educators who were dissatisfied with the dual system sparked a philosophical debate that became known as the Regular Education Initiative (REI). Initially, the REI movement advocated for the return of students with mild learning disabilities from separate and pullout programs to regular education classrooms. In time, other educators and parents began to argue for the return of students with more severe disabilities from separate, segregated schools and self-contained classrooms to programs within their neighborhood schools.

In 1986, Congress passed Pub. L. No. 99-457, expanding special education services to include birth through 5 years of age. The individual education plan for very young children with disabilities is called the Individualized Family Service Plan (IFSP), and may include services for the family as well as the child. The intent was early intervention to meet the multiple needs of infants, toddlers, and preschool-aged children with medical and developmental difficulties.

In the 1990s, the philosophical debate and REI movement evolved into what is commonly known as the inclusive schools movement or inclusion. *Inclusion* refers to the maximum integration, with

support, of students with disabilities, regardless of severity in general (the term is synonymous with *regular*) education classrooms. At the beginning of the inclusive schools movement, Pub. L. No. 94-142 was reauthorized in 1990 as Pub. L. No. 101-476 and the Education for All Handicapped Children Act was renamed Individuals with Disabilities Education Act (IDEA). The 2004 reauthorization with the updated name, Individuals with Disabilities Education Improvement Act (still called IDEIA) contains expanded provisions regarding parents, teachers, paraprofessionals, assessment, eligibility, discipline, due process, and transition services.

Philosophical debates regarding the special education curriculum, and optimal ways to serve the academic and related needs of students with disabilities persist. At the beginning of the 21st century, special education is being examined through a variety of lenses, such as disability studies, deaf culture, democratic schooling, and multicultural education.

## SPIRAL CURRICULUM

---

The spiral curriculum is a key feature of the curriculum design process popularized through Jerome Bruner's post-*Sputnik* classic, *The Process*

*of Education*. Although John Dewey wrote of a similar principle, his notion of spiraling focused on the learner's experience and the interrelatedness of all areas of knowledge. In contrast, Bruner based his spiral in the structure of separate academic disciplines as provided by university scholars. A central notion was that basic principles in any discipline can be represented in some intellectually honest form to even very young children and that this process would build in the readiness for them to engage in later and progressively more complex presentations of the principles. Writing in 1960, Bruner emphasized the advantage of teaching structural principles because of the recent explosion of new knowledge to include in the curriculum, especially in the sciences. Amid the nearly hysterical atmosphere of the cold war and the flood of government money that accompanied it, acceptance of this discipline-based approach mushroomed, making it the model for national curriculum reform for nearly a decade. Although a variety of circumstances dampened enthusiasm for the model by the end of the 1960s, it helped establish the hegemony of disciplinarity among other concerns of curriculum design.

Bruner's ideas were first published as a report on the Woods Hole Conference of 1959, a meeting attended primarily by scientists, mathematicians, and psychologists. Their conclusions, as interpreted by Bruner, established several themes to guide curriculum work. Bruner believed the first two—understanding new concepts as part of the overall structure of a discipline and discovery learning—led naturally to the third, the spiral curriculum. For example, in the overall structure of algebra, "balance" is a key concept. A spiral curriculum might take advantage of young children's intuitive understanding of the concept through discovery lessons using toys such as teeter-totters, then circle back to the concept later using various forms of levers, and eventually provide for the discovery of the meaning of relationships expressed in abstract algebraic equations.

Bruner, a cognitive psychologist, believed like many curriculum scholars that education should lead to understanding, not mere performance, and that this goal was best achieved through discovery learning. However, as he noted in *The Process of Education*, psychologists had neglected the study of curriculum problems for most of the 20th century.

That, plus the exclusion of curriculum professors and teachers from the Woods Hole conference, added up to his failure to sufficiently address long-established concerns of curriculum scholarship, such as the goal of democratic citizenship, the nature of the individual student, and relevance of the curriculum to the learner's life. Bruner's proposal treated all students as miniature scholar-specialists. He later admitted that one mistaken assumption of the discipline-centered reforms may have been that students would be as excited about mastering the curriculum as the disciplinary specialists had been about constructing it. He also noted his failure to consider elements of the context of learning, especially culture.

Other weaknesses aided in the model's demise as the reigning curriculum model of the post-*Sputnik* era. Scholars within a discipline could not always agree on its structure. Others felt there was a tendency to impose methods of curriculum development for the sciences on all subject areas on the assumption that all disciplines had similar structures. The fact that university scholars with little or no public school experience were creating curricula sometimes led to misuse or rejection of their products by teachers. When politicians of the mid-1960s called for evaluation studies of federally funded curriculum reform, the results undermined confidence in top-down programs created with no teacher input, further eroding the model's popularity.

Although many curriculum developers continue to use the principle of discipline-based spiraling, critics cite a frequent tendency of their product to be flat, that is, to include little substantive development of concepts at successive levels. In addition, curriculum scholars note that discipline-based spiraling ignores the macrocurricular function of general education, neglecting practical, and interdisciplinary knowledge.

## SPIVAKIAN THOUGHT

---

Gayatri Chakravorty Spivak (1942– ) is a scholar renowned for her critique of postcolonial studies, her critical translation of Jacques Derrida's philosophy, and the provocative question she raised in a 1988 essay, "Can the Subaltern Speak?" Her answer was a resounding "no," an assertion stimulating much analysis and debate since that time. Spivak was born in India and received an undergraduate English degree from the University of Calcutta and graduate degrees from Cornell University. Her scholarship, which transgresses disciplinary and theoretical boundaries, draws from literary criticism, poststructuralism, Marxism, deconstruction (particularly Derrida), feminism, and cultural studies. She has produced incisive critiques of imperialism, historiography (the theories and practices of historical research), academia, knowledge construction, globalization, international feminism, and terrorism among others. Her work demonstrates unrelenting concern for the silencing of "subaltern" subjects. In 1976, Spivak garnered acclaim for her self-reflexive translation of French deconstructionist Derrida's *Of Grammatology*. Since then, she has published dozens of critical texts, essays, and literary works. In the last two decades, critical educational scholars have applied Spivak's rich theorizing to the field of curriculum studies in varied ways.

Spivakian thought animates the field of curriculum studies most notably through the critical questions it prompts concerning the power of knowledge production, the representation of marginalized voices, and the forms in which resistance is enacted. Who speaks and who is silent? Who has the right to speak for whom? What counts as speech? How can the interests and voices of marginalized people (the subaltern) be represented? How can subaltern people influence the production of knowledge?

Such questions are significant for a field of study that creates knowledge and determines whose views, beliefs, and knowledge will dominate in educational spaces. Indeed, such questions crystallize a component of Spivakian thought critical to curriculum studies: the imperative to interrogate institutions, discourses, and practices constitutive of knowledge production—the academy, canonical theory, activism, even critique. Her interrogative impulse proceeds from the understanding that academic practices and discourses wield significant power in inciting and suppressing voice, erasing and representing subjects, and fueling or obstructing social justice.

Spivak's critique of postcolonial studies—itsself a critical field—and advocacy for subaltern subjects are key resources for scholars concerned with questions of power, voice, representation, and justice. Through Spivak's scholarship, the concept of the "subaltern" gathered renewed momentum as a signifier for groups relegated to the periphery of society and history: the poor, women and children, the working classes, the disenfranchised. In her well-known essay foundational for feminist, postcolonial, and subaltern studies, "Can the Subaltern Speak?," Spivak emphasized the impossibility of representing—and hearing—the voices of subaltern subjects. Her argument emerged through her analysis of a critical collective's work during the 1980s that critiqued traditional Indian history for its elitist and imperialist leanings. She affirmed the deconstructive impulse of the group, their critique of the power shaping knowledge construction, and their advocacy for marginalized voices in dominant narratives. However, she also argued the group's work to represent marginalized voices constructed frozen and universalizing (essentialist) representations that erased subaltern subjectivity and agency—a form of violence that repeated the representational crimes committed in the archival past and made hearing subaltern voices impossible. Enduring questions that Spivak's critique of postcolonial studies engender for curriculum scholars is how to disrupt official curriculum that legitimizes what counts as knowledge and create educational spaces in which subalterns can articulate their own diverse knowledge and perspectives. In such impossible circumstances of representing voices that cannot possibly speak and be heard through dominant accounts, Spivak does not

advocate "better" accounts of marginalized people or abandoning representational efforts altogether. Instead, she suggests that scholars use the inevitably partial, fraught, but necessary tool of "strategic essentialism," to pursue greater political good.

Curriculum scholars have drawn from Spivakian thought to analyze the complexity of subaltern status, create educational spaces that foster speech, advocate teaching as activist intervention in the workings of power, and expand understandings of what constitutes speech. For example, activists have defined strategic uses of the body in classrooms, silent demonstrations, and theater as expressions of voice. Others have revised dominant groups' historical accounts to include the contributions of underrepresented people (such contested efforts are evident in "new history" and the "culture wars"). Some have tracked fluid and contested expressions of oppression and privilege wrought by globalization, technology, and media. Some have critiqued both the romanticized construction of silenced voices (not necessarily noble or progressive) and of subaltern studies as savior to the disempowered (itself a form of power). In addition, a particularly useful critique has centered on dominant groups' cooptation of minority status to articulate their feelings of victimization and to conflate, problematically, personal feelings with structural oppression. For example, some White, heterosexual, and Judeo-Christian people have claimed they are "oppressed" as subaltern groups have challenged their power. Spivakian thought thus animates diverse analysis of educational power and varied critical struggles to enable rather than restrict voice.

## STANDARDS, CURRICULAR

---

Curricular standards are the student learning goals for a particular curriculum content area with designations for specific grade levels. Standards typically include intended learning outcomes in the areas of knowledge, skills, and understandings of basic concepts, along with structure of the discipline. Students are expected to demonstrate mastery of these standards primarily through performance on assessments. National professional organizations of teachers and teacher educators generate these standards, which often are grouped according to broad concepts such as “number sense.”

Although curricular standards are set by national professional education associations, each state has developed its own set of learning goals for its students by content area and grade level. Because of the existence of national standards, most states’ standards are remarkably similar because the states use the national standards as a guide in developing their own state standards. These state standards go by different names such as Texas Essential Knowledge and Skills (TEKS), Arkansas Curriculum Frameworks, California Content Standards, and New York Curriculum Standards. Whatever the name, they are state curricular standards.

In recent history, the curricular standards came to the forefront as a response to the 1983 report, *A Nation at Risk*. In the report, the U.S. educational system was decried as overall a mediocre system, and a call was issued to improve the quality of U.S. education. Curricular standards were examined and revised to reflect high expectations of academic achievement for U.S. students. Also central to this reform movement was the emphasis on assessment. By tying assessment to curriculum standards and using the assessment results for school ratings, curricular standards reached an importance never attained previously. Although curricular standards existed before 1983 and professional organizations

and researchers attended to these standards, the standards were not embraced by the school practitioner until school ratings were based on student achievement on assessments based on these standards. The Goals 2000 issued in 1990 further elevated the importance of curricular standards because they called for all students in 4th, 8th, and 12th grades to leave school having shown mastery of rigorous academic standards. Professional organizations responded with revised standards, and public schools wrote curricula based on these stringent standards. Four major content areas with national curricular standards are science, mathematics, English language arts, and social studies. The National Science Teachers Association, the National Council of Teachers of Mathematics, the National Council of Teachers of English, and the National Council for Social Studies have developed standards in their content areas.

Most practitioners recognize curricular standards as goals of a discipline that students are expected to master whether a process, skill, or understanding. This definition looks to schools to achieve these standards with student outcomes. However, some professional organizations such as the National Council of the Teachers of Mathematics include vision in their standards.

The current importance of curricular standards is apparent when examining state level student academic achievement tests mandated by the No Child Left Behind Act (NCLB). Each state develops its annual achievement tests for third through 8th graders and high schoolers by testing students on the curricular standards for reading, language arts, mathematics, science, and English proficiency at the appropriate grade level. States issue grades to students, schools, and school districts—based performance on the curricular standards, and the grades are made public. Some states require students to demonstrate mastery of these curricular standards through the state assessment before the student is promoted to the next grade level or is allowed to graduate from high school.

Historically, curricular standards have been around for as long as we have had schools. There have always been learning goals for students and even testing based on these curricular standards is not new. What is new is the network of state standards engendered by the federal government’s NCLB. In the era of the one-room schoolhouse,

curricular standards were set by counties or local school districts and promotion from 8th grade required passing a county exam. Failure to pass the county exams reflected on the students, not the school. The focus on state standards across the nation coupled with high-stakes testing and the federal government's withholding of funding for schools that do not make progress is what differentiates the current curricular standards movement.

The curricular standards movement as part of the school reform movement has become a political hot potato for local schools. Although the focus on education as a national priority is good news to educators, many question the methodology used to ensure students master high standards. The political rally cry has been that "high standards = high achievement," and public figures rely on test results to show students are achieving these high standards.

Then there are those that would argue that we cannot label curricular standards as "high" because that denotes they are above the average standards. Once we have a majority of our students achieving these standards, they become the average or normal standard, not a high standard. Hence, planned obsolescence. Another group of people state that because knowledge is fluid and ever changing we cannot pin down "high" curricular standards. As our knowledge base expands and is sometimes transformed, as physics was in the emergence of quantum physics, curricular standards must be revised.

From a political scientists and sociologist's viewpoint, curricular standards are suspect in that they convey the current view of what an educated person should know. This is largely dictated by our culture and workplaces. Many critical theorists decry curricular standards as discriminating against minorities, low-socioeconomic students, and English language learners. Although curricular standards were revised in the 1980s and 1990s to embrace challenging learning expectations for all, there have been unintended consequences such as increased dropout rates among minorities and the urban poor. Raising curricular standards without raising resources and making improvements in teacher training will not serve U.S. education.

In addition to the curricular standards for public school students PreK–12, curricular standards also exist for the education of teachers in each of

these content areas and for institutions of higher education.

## STANFORD UNIVERSITY COLLECTIVE OF CURRICULUM PROFESSORS

---

The College of Education at Stanford University served as a collective for curriculum studies through the influence of Paul Hanna and Fannie Shaftel on social studies curricula from the end of World War II through the 1960s; the substantial scholarship of Elliot Eisner, Decker Walker, and Nel Noddings in the last three decades of the 20th century; and the influence that educational scholars in research on teaching (Nathaniel Gage), educational history (David Tyack and Larry Cuban), educational measurement and evaluation (Lee Cronbach), teacher education (Lee Schulman), and school administration and reform (Linda Darling-Hammond) have provided to curriculum scholars. Numerous other scholars, having studied at Stanford, are significant contributors to curriculum studies.

The College of Education was fashioned by Elwood P. Cubberly, recruited by the president of Stanford, David Starr Jordan. Starr served as a mentor for Cubberly in his early academic career at Indiana University. Established with Cubberly as dean in 1917, the college's initial focus was educational administration. An exception to

Cubberly's focus on school leadership was the appointment of Harold Benjamin as associate professor of education and psychology until 1931. Benjamin, a graduate of Stanford, developed his fictional alter-ego "J. Abner Peddiwell" in lectures at Stanford, eventually emerging in print in *The Saber-Tooth Curriculum*.

With Cubberly's retirement in 1933, Grayson Kefauver recruited Harold Hand and Paul Hanna in 1935 to promote a more progressive orientation to the college. Hand, whose specialization was in secondary education and guidance, left for the University of Illinois after World War II; Hanna became a fixture at Stanford until his retirement. Hanna's early work was in promoting elementary school curricula based on integrative units, combining subjects thematically, particularly in the social studies. Hanna was also editor of a series of magazines for elementary schools, *Building America*. This periodical emerged from Hanna's work with the Society of Curriculum Study at Teachers College Columbia and was widely adopted in schools across the country, but came under criticism in 1946 when the California Society of the Sons of the American Revolution contended the series was a tool of communists in promoting social studies over classic studies in history and geography. The controversy resulted in reactionary legislation by California lawmakers and the *Building America* series was target of red-baiting for the next five years. Hanna spent much of the 1940s successfully lobbying the federal government for research grants for Stanford and in the 1950s turned his attention to international projects. His evolution from problem-centered education to a more hierarchical conception of curriculum is reflected in his promotion of a national curriculum center in 1959.

Elliot Eisner achieved his doctorate in education from the University of Chicago and was appointed as associate professor of education and art at Stanford in 1965. Eisner's emphasis on aesthetics and the imagination in teaching and learning are reflected in his approach to curriculum development and evaluation. Critical of the widespread acceptance of instructional behavioral objectives, Eisner suggested predetermined goals are particularly ill-suited when engaged in aesthetic expression where it is often preferred to provide activities that have no prespecified outcome. In the 1970s,

Eisner crafted "educational connoisseurship" an enduring model of curriculum inquiry and evaluation employed as an alternative model for validating curriculum research and expanding scholarship to consider portrait and fiction as meaningful forms for insight. Eisner also provided a framework for understanding options in contemporary curriculum thought through development of five distinct orientations to the curriculum: (1) the development of cognitive processes, (2) academic rationalism, (3) personal relevance, (4) social reconstruction and adaptation, and (5) curriculum as technology.

Eisner's students have evidenced his influence with attention to aesthetics as a powerful feature in curriculum scholarship and the exercise of imagination as a dimension of creative and meaningful inquiry. Decker Walker is particularly notable given his tenure at Stanford is nearly as long as Eisner's. Walker's initial scholarship on how curriculum committees develop a curriculum produced a "naturalistic" model of curriculum development is an important alternative to the Tyler Rationale. Observing that development is largely political rather than methodical, he identified three dimensions in curriculum construction: (1) the *platform* is where committee members bring their convictions and dispositions before the committee to vie for acceptance; (2) in *deliberation*, participants engage in transactions to determine which curriculum policies are most defensible in the political setting; and (3) curriculum design results and policies are put in place as time constraints end negotiation.

With Jonas Solits, Walker authored a brief volume on curriculum aims with the intention that the book be used in foundations courses to introduce the topic of curriculum theory to students through consideration of important historical and contemporary writers on curriculum. In 1990, Walker provided a comprehensive statement on curriculum, evolving from a construct proposed by Hilda Taba. A synoptic text on historical and current scholarship on curriculum, curriculum considerations were examined in a variety of ever-widening contexts (e.g., the classroom, the school, and national perspectives), stressing change in curriculum policy and practice be informed by grounded theory and reasoned deliberation. The work is consistent with Walker's earlier naturalistic design in the context of contemporary scholarly writing

on curriculum. Walker's scholarship in the 1980s and 1990s expanded to the relationship of technology to curriculum and instruction.

Nel Noddings, a member of the Stanford faculty in 1977 until 1998, offered a novel proposal that considered current scholarship on moral development and women as well as advancing curriculum notions of John Dewey, contending caring be a principal concern of education. Articulated in her 1984 work, *Caring: A Feminine Approach to Ethics and Moral Education*, Noddings provided a model for reconstruction of the school curriculum around expanding considerations of care for self, people, ideas, and the planet. In thoughtfully attending to these ever-wider circles of engagement and concern for relationship, activity is directed to develop empathic understanding and responsiveness. Noddings developed recommendations for school reform based on this curriculum proposal and has made substantial contributions to the philosophy of education and moral development theory.

## STENHOUSE, LAWRENCE

---

The conceptualization of “curriculum as a means to an end” underlying current educational practices including the use of standards and authentic assessment can be traced to the work and theorizing of Lawrence Stenhouse (1926–1982). Stenhouse, a British educational theorist, framed curriculum as hypothesis and called on teachers to

use an inquiry approach to develop a rigorous curriculum that promoted higher-order thinking skills and honored and attended to cultural diversity. Curriculum as a set of hypotheses moves paradigmatically away from a positivistic approach toward a metaphoric/humanistic one. Teachers then, as artistic professionals, are asked to recreate educational standards in ways that hold all students accountable for interpreting texts and constructing individual understandings.

Stenhouse is regarded as a pioneer who contributed to reshaping curriculum as a field of study during the 1970s. His masterpiece, *An Introduction to Curriculum Research and Development*, is widely known as one of the key foundational texts, alongside Ralph Tyler's *Basic Principles of Curriculum and Instruction*, and Joseph Schwab's “practical papers.” Stenhouse argued that curriculum research and development should be within the purview of teachers.

Stenhouse's research deals particularly with the practical nature of curriculum problems, and Stenhouse and his collaborators from the United Kingdom extended their work into the areas of teacher research and educational change. As a visionary and practical thinker, Stenhouse offers insight into education reform in general and curriculum studies in particular.

In 1967, Stenhouse became director of the Humanities Curriculum Project (HCP), funded by the Nuffield Foundation and School Council (1967–1972), with the purpose of centering value-laden social and cultural themes in secondary education curricula. The HCP work included a team of eight people collaborating over 3 years. Briefly, Stenhouse attempted to mount an approach to a difficult set of teaching problems pertaining to race relations in which teachers carry heavy research and implementation responsibilities. Some of Stenhouse's views articulated in the context of the HCP may be questioned in the 21st century. For example, Stenhouse asked teachers to take a neutral position in the discussion on race relations, and this may be particularly problematic for scholars connected to critical race theory. Still, in the broader context of the contemporary standards-based education movement, the HCP exemplifies a kind of standards-based reform package that meets the need for developing richer, more meaningful curriculum content. Stenhouse foreshadowed

contemporary meanings of standards when he came to theorize the multiplicity of standards as value-judgments that require teachers to be critics who assess the worth of the contributions children make as individuals to the culture of the class. Here, his higher vision regards the curriculum not as the materials of instruction, but rather as the basis of the students' discussion and thinking.

Stenhouse made three major contributions that advanced the curriculum field. First, indebted to Schwab's theory of curriculum deliberation, Stenhouse diagnosed the field of curriculum as problematic because of its heavy reliance on both R. S. Peters's metaphysic for purified aims and the Tylerian objectives model. Alternatively, he developed *the process model* in which teachers' practical and procedural thinking are encouraged with aims of achieving a balance between ends and means, ultimately identifying the better, if not the best, curricular solution. This process model expands the purview of curriculum and thus serves as a basis on which the notion of the teacher as decision maker, a prominent theme in teacher education literature, is made possible.

Second, Stenhouse reconfigured the notion of curriculum research and evaluation through the HCP project, emphasizing a utilitarian purpose that benefits those who teach on the front lines of education. Relying partially on Robert Stake's early version of the responsive evaluation model, he reenvisioned the function of curriculum research and evaluation, placing teachers as both curriculum developers and evaluators in the articulation of intent, process, and outcome. This widened the scope of qualitative curriculum research and evaluation and prompted teacher researchers to adopt new qualitative inquiry paradigms to guide classroom action research. Stenhouse passionately advocated for teacher autonomy and self-assessment as powerful tools by which to enhance quality education. The classroom is seen as a place where teachers and students conduct research on problems inside and out of the classroom.

Third, Stenhouse opened the door to a new educational movement for, with, and by the force of teachers. Australian scholars such as Stephen Kemmis and Robin McTaggart in the 1980s adopted Stenhouse's vision of the teacher-researcher and incorporated it into a discourse of critical theory. In the 1990s, this trend toward teacher-centered

educational improvement continued to blossom in the United States and in international contexts. The teacher-research movement makes more sense when connected to what Stenhouse called *emancipation*, a theme deeply grounded in his later writing. Emancipation enables teachers and allows them to attain a position as knowledgeable, sensitive, thoughtful, and professional. Stenhouse's unique vision of teacher emancipation is convergent with progressive self-criticism and professional ethics in which teachers inextricably intertwine ethical matters with issues of student learning and growth.

The impact of Stenhouse's work on the field of curriculum is explicit. His view of curriculum as hypothetical at the classroom level implies the ultimate necessity of achieving legitimacy for teacher research through which official knowledge becomes more culturally relevant and sheds light on contemporary versions of culturally responsive pedagogy. His vision in which students freely exercise higher-order thinking as they engage humanistic texts is still a valued aim of contemporary education. Further, his reenvisioned role for teachers as supporters of student knowledge construction through the ongoing development and evaluation of curricular experiences aligns with recent arguments for professionalism and teacher autonomy. Stenhouse's theoretical frameworks for curriculum and teacher research will remain classic as long as dedicated educators continue to search for local curriculum theories and meaningful curriculum implementation under the banner of collaborative teacher research.

## STRATEMEYER, FLORENCE B.

---

Florence B. Stratemeyer (1900–1980) made profound and long-lasting contributions to the field of curriculum and fostered the development of teacher education as a field of study. Stratemeyer's most significant contribution to the field of curriculum studies was the 1947 publication, *Developing a Curriculum for Modern Living*, which she coauthored with Hamden L. Forkner and Margaret G. McKim. In this work, the authors posit that those responsible for developing curriculum should go beyond the creation of broad goals and specific skills, and consider the sequence and continuity of student experience. They address the significance of acknowledging and incorporating student experiences outside the classroom, and identify everyday concerns emerging from “persistent life problems” of the learner as the necessary foundation for teaching and learning. These comprehensive concerns are organized into the categories of health, intellectual power, moral choices, aesthetic expression and appreciation, person-to-person relationships, intergroup relationships, natural phenomena, technological resources, and economic-social-political structures and forces. Though the authors do not propose that these persistent life situations should be a definitive guide for curricular planning, they put forward that these concerns build meaningful connections between the learner and the subject matter to be taught and provide the impetus for active and engaged learning. The authors contended that curricular design must accommodate the unique development levels and learning styles of those that it serves, and warned that failure to do so could result in wasted time or worse—students learning information that will not facilitate their eventual contributions to society.

In this and other works, Stratemeyer reconceptualized the role of teacher as not merely a director of learning, but as a guide in a student-centered, democratic environment. She believed that teacher candidates should evolve as critical, independent

thinkers who would strive to encourage student achievement to the highest possible level. In a time of low standards and moderate goals, Stratemeyer's foundational principle of teacher education was to foster scholars who approached curricular decision making through the lens of “reasoned beliefs.” A professor of education at Teachers College, Columbia University, from 1930 to 1965, she also earned her bachelor's, master's, and PhD at that institution. At Teachers College, Stratemeyer was instrumental in the identification of teacher education as a legitimate, respected field of study. Likely unbeknownst to her, her theoretical and pedagogical decision making became the standard of excellence for teacher preparatory programming around the country. She contributed many noteworthy publications to the field of teacher education. In 1948, she coauthored the *School and Community Laboratory Experiences in Teacher Education*, or “The Flower's Report.” This influential work surveyed developments in teacher preparatory programming in the previous decade, organized evolving patterns, and elucidated the possibilities that could be realized through employment of professional laboratory experiences by identifying nine guiding principles for that practice. Stratemeyer contributed other prominent works, including five chapters in the 1968 publication *Teacher Education for a Free People, Working With Student Teachers, and New Horizons for the Teaching Profession* in 1961. In 1965, the American Association of Colleges of Teacher Education published her sixth Hunt Lecture: “Perspectives on Action in Teacher Education.” In this address, Stratemeyer identified and offered her view on eight ongoing challenges in teacher education.

Stratemeyer was also instrumental in the development of the groundbreaking New School at Teachers College, and its premise clearly reflected her theoretical and pedagogical beliefs. With Thomas Alexander and other faculty, Stratemeyer developed an innovative preparatory program to cultivate teachers with unique insights and skills. The theoretical underpinning and goal of the New School was to develop teacher candidates who were inherently responsible for contributing to the rebuilding of a devastated, Depression-era society. This innovative learner-centered curriculum required teacher candidates to spend a summer working and learning on a 1,800-acre farm in

North Carolina, as well as to seek employment in the public sphere. Whether they were engaged in a foreign country or waiting tables in a Manhattan restaurant, the purpose of these requirements was to facilitate teacher candidates' understanding of the unprecedented experiences and challenges of families living in the United States in the 1930s. The New School was in operation from 1932 through 1939.

These works shed only partial light on Stratemeyer's commitment to excellence in teacher preparation; some would say her most significant contributions were made through her profound dedication to the many students with whom she worked. Stratemeyer genuinely appreciated and valued her students; she fostered their unique contributions to the field while perpetually explaining and questioning her own. She was dedicated to nurturing students' analytical and critical thought, often asking, "On what basis do you say that?" in classroom discourse. In her decades of service at Teachers College, Stratemeyer worked with several thousand master's students and advised approximately 150 successful doctoral students, many of whom went on to become leaders in the field. Some of her doctoral students include Margaret Lindsey, Dorothy McGeoch, and Martin Haberman. Haberman has written several pieces about his work with Stratemeyer. In one, he recalls Stratemeyer possessing the utmost consideration and intellectual deference for all of her students, remembering names and research trajectories with an almost uncanny accuracy. He recalled the specificity with which Stratemeyer fostered each student's writing, which included individual planning conferences and purposeful drafting with extensive feedback from the professor. Stratemeyer was the consummate teacher of teachers; her legacy carries on in the accomplishments of the thousands of students with whom she worked over the years.

## STRUCTURALISM

---

*Structuralism* is a conceptual and methodological approach to describing and analyzing a variety of objects of inquiry including, for example, cultures, economics, language, literature, mythologies, politics, and societies. A structuralist analysis assumes that these objects of inquiry can be characterized by underlying structures conceived as systems of interrelated parts and that they can be defined (at least in part) by relationships among these constitutive elements. Structuralist assumptions (concerning both the existence of underlying structures and the methods by which they should be analyzed) developed within what we now tend to label "Continental" (that is, non-Anglophone European) philosophy—much of it French—during the early decades of the 20th century, but the influence of structuralism on both Continental and Anglo-American scholarship became much more prominent after World War II.

From the late 1940s through the 1970s (and to a diminished extent beyond), structuralist thought had a significant and explicit purchase on disciplines such as anthropology, cognitive development, literary criticism, mathematics, political science, and sociology. In retrospect, we can also discern implicit structuralist assumptions in the literatures of educational research and curriculum inquiry during this period. For example, two of the most influential curriculum texts in the immediate post-World War II era were Ralph Tyler's 1949 *Basic Principles of Curriculum and Instruction* and Benjamin Bloom and colleagues' 1956 *Taxonomy of Educational Objectives*. Neither of these texts proselytizes for structuralism nor do they cite structuralist literatures, but both texts appear to be replete with structuralist assumptions

and to invoke structural principles in their reasoning. Exposing, naming, and criticizing the structuralist assumptions that continue to pervade contemporary curriculum texts, discourses, and practices has largely fallen to scholars who adopt poststructuralist positions.

### A Brief History and Characterization

One of the earliest influences in the development of structuralism was Ferdinand de Saussure's *Course in General Linguistics*, a text published posthumously in 1916 that was compiled by his colleagues from students' notes of a series of lectures he gave at the University of Geneva from 1906 to 1911. Saussure applied structural analysis only to linguistic systems, but many Continental philosophers and intellectuals chose to apply his reasoning more widely, and his assumptions and methods were subsequently modified and extended to other disciplines and to nonlinguistic phenomena. Structuralism was increasingly taken up within fields such as anthropology, psychoanalysis, literary theory, and architecture so that by the 1960s and 1970s it had to a large extent eclipsed phenomenology and existentialism.

Structuralism assumes that all human social activities—the clothes we choose to wear, the books we write, the cultural rituals we practice—constitute languages and that their regularities can therefore be codified by abstract sets of underlying rules. Thus, for example, the psychoanalyst Jacques Lacan asserted that the unconscious was structured like a language, and Michel Foucault's early writings characterized knowledge about what can be spoken of in a discursive practice. Some of the distinctive properties of structuralism and its effects can therefore be appreciated by considering a number of Saussure's assumptions, assertions, and methods and seeing how some or all of these appear to underlie the reasoning and arguments of educational texts such as Tyler's rationale for curriculum development and Bloom's taxonomy of educational objectives.

According to Saussure, language is structured before its realization in speech or writing. Language consists of a set of *signs*, each of which is constituted by a *signifier* (a sound or inscribed image) and a *signified* (a concept or meaning). Other scholars use different words for *signifier* and

*signified*, and most add a third aspect to Saussure's linguistic *sign* to include nonlinguistic objects or referents. For Saussure, signs are arbitrary because a word (*signifier*) is linked to a concept or meaning (*signified*) by the conventions and common usages of a particular speech community. Signs do not exist outside of a system and a word's meaning is determined by its relationships to, and differences from, other words, with the result that binary distinctions or oppositions tend to determine the content and normative commitments of the structure. Saussure also distinguished *langue* (language) from *parole* (speech), and his structural linguistics focuses on language (the totality of signs that constitute a natural language, such as French or English) and not on particular utterances. Saussure's analytic method examines language at one moment in time—a static snapshot of a constantly changing system—which moved semiology from *diachronic* to *synchronic* analysis. Thus, Saussure's structuralist linguistics appears to be ahistorical, a much-criticized (especially but not only by poststructuralists) characteristic that it shares with many other manifestations of structuralist thought. Finally, structuralist analysis of sign systems focuses on describing and mapping relationships, categories, and classifications and thus tends to represent itself as an ideologically neutral method. The cloak of ideological neutrality has led some critics to associate (or conflate) structuralism with positivism, but not all knowledge claims that arise from structuralist arguments can be taken as positivist.

When structuralist thought is applied to studies of society and social relations, the individual human subject is decentered. Structuralism questioned the salience of individual agency and sought to explain social interaction in terms of its predetermination by underlying social structures. For example, during the 1940s, Claude Lévi-Strauss initiated a program of structural anthropology that sought to identify the structures that determine cultural practices and myths across societies. In his 1949 book, *The Elementary Structures of Kinship*, Lévi-Strauss applied structuralist reasoning to his examination of kinship systems across cultures and demonstrated that social arrangements that appeared to be different could plausibly be understood as permutations of a small number of underlying kinship structures.

By the early 1960s, many Continental scholars were working with structuralist ideas, although many resisted being labeled as such and some eventually became more identifiable as poststructuralists. For example, Roland Barthes and Jacques Derrida explored structuralist approaches to literary criticism (although Derrida now is chiefly associated with deconstruction, which is a complex response to several theoretical and philosophical movements, especially phenomenology, psychoanalysis, and structuralism) and, as already noted, Jacques Lacan applied Saussure's structuralism to psychoanalysis. Methods of structural analysis (as distinct from structuralist assumptions) appear to have informed Jean Piaget's studies in developmental psychology, although he is more likely to have described himself as constructivist. Foucault explicitly denied his affiliation with structuralism in his later works, but his 1966 book, *The Order of Things*, seeks to explain how structures of epistemology (*episteme*) in the history of science have determined the ways in which we imagine knowledge and knowing. Thomas Kuhn also investigated the structured production of scientific knowledge and methods in his 1962 book, *The Structure of Scientific Revolutions*, which demonstrated how the conventions of scientists' speech communities shape standard practice and discourage deviations from "normal science" under most circumstances.

Louis Althusser also decenters the human subject in his structuralist interpretation of Marxism, in which he argues that individual agency and social interaction is predetermined by social structures, namely, *ideological state apparatuses* that reproduce capitalist relations of exploitation in the interests of the ruling class.

### Structuralist Thinking in Curriculum

Cleo Cherryholmes demonstrates (in his 1988 book, *Power and Criticism*) that many of the characteristics of structuralist thinking described earlier are pervasive (albeit unacknowledged) ways of thinking about education. Structuralist thinking in education foregrounds order, organization, and certainty, which Cherryholmes illustrates by exposing the structuralist assumptions, methods, and reasoning in Tyler's *Basic Principles of Curriculum and Instruction* and Bloom and colleagues' *Taxonomy of Educational Objectives*.

Tyler's Rationale is an approach to thinking systematically about curriculum and instruction that unequivocally imposes structuralist assumptions on those who use it by requiring them to

1. Define learning objectives
2. Select useful learning experiences
3. Organize experiences to maximize their effect
4. Evaluate the process and revise where needed

The structuralist characteristics of this rationale include the following:

- The four steps define and regulate curriculum, but the individual steps have no meaning outside of the system in which they are located; their curricular meanings are determined by the relationships among steps in the process. For example, learning objectives have little meaning when considered in isolation, but become meaningful in a systematic structure of organized learning experiences and evaluation. Similarly, an evaluation instrument has no meaning in isolation but becomes significant in the context of learning objectives and experiences.
- Binary distinctions and oppositions (many of which are tacit) determine the content and normative commitments of Tyler's rationale: purposeful/purposeless, organization/disorganization, accountability/nonaccountability, continuity/discontinuity, sequence/nonsequence, evaluation/nonevaluation. Readers are left in no doubt about which term in each pair is valued by the structure.
- Tyler's Rationale is ahistorical insofar as objectives, learning experiences, their organization, and evaluation are analyzed by reference to an immediate situation rather than to their historical antecedents.
- Tyler's Rationale is represented as an ideologically neutral design process.
- Tyler's rationale decenters the agency of teachers and learners by assuming that structural relations—among objectives, learning experiences, their organization, and evaluation—determine the curriculum and its meanings.

The full title of Bloom and colleagues' 1956 book, *Taxonomy of Educational Objectives. The Classification of Educational Goals, Handbook I: Cognitive Domain*, excessively overdetermines its structuralist credentials (even though its authors do not cite a structuralist literature). The book begins with an epigraph that quotes *Webster's New Collegiate Dictionary's* (1953) definition of taxonomy as the "classification, esp. of animals and plants according to their natural relationships," a definition that emphasizes that a taxonomy is more (that is, more structured) than a simple classification. The authors aspire to constructing a taxonomy in which the order of its terms corresponds to some "real" (their "scare" quotes) order among the phenomena represented by the terms. But the authors also recognize that taxonomies are social constructions and admit that terms and titles are often quite arbitrary. This juxtaposition of their acknowledgment of the arbitrariness of a sign with their desire for a sign to represent something that is "real," is an eloquent (though almost certainly unintended) reminder of structuralism's limitations and contradictions.

Drawing further on Cherryholmes's analyses of selected educational texts, Bloom and colleagues' taxonomy exemplifies several characteristics of structuralist reasoning:

- As the authors admit, the particular form of the taxonomy is arbitrary.
- The meaning and value of any one educational objective is determined by its relationships with other objectives (since assumptions about "real" or "natural" relationships are a guiding principle of the taxonomy); these meanings and values are produced in large part by binary distinctions between the taxonomy's categories, such as, comprehension/knowledge, application/comprehension, analysis/application, and so on (with the normative commitments being clearly signaled by the first-named terms in each pair being at a "higher" level in the taxonomy than the other).
- Human actors (teachers and students) are decentered because curricular values and meaning are located in structures external to individuals.

- The authors repeatedly and emphatically assert the taxonomy's value neutrality, claiming that it is "purely descriptive."

### Structuralism Now

Many contemporary scholars now reject an overly deterministic interpretation of underlying structures and instead seek a more dialectical, or mutually constitutive, relationship between agency and structure. For example, Anthony Giddens argues for "structuration theory" in sociological analysis as one way to avoid privileging either structure or agency. He suggests that individual actions are informed by social interaction and an awareness of structural contexts, that is, the interactions between individual agency and structural contexts determine both processes and outcomes. Foucault also reconceptualized the relationships of structure and agency by addressing questions about (for example) *how* structures appear to determine some things and not others, *how* agency is provided to some and denied to others, and *how* relationships between structure and agency come to be discursively constituted. Foucault's emphasis on determining historically located relationships between language, knowledge, power, and institutional practices distances his work from the ahistorical tendencies of earlier structuralists.

Many critics of structuralism now identify themselves as poststructuralists. The terms *structuralism* and *poststructuralism* are not binary opposites, and indeed, they have a number of continuities. Structuralists and poststructuralists share the view that the objects, elements, and meanings that constitute our "existential reality" are social constructions—they cannot be presumed to exist independently of human perception and activity. For example, a strictly structuralist orientation in semiotics would seek to identify and describe the codes and systems of signification with which we articulate experience and produce meaning. A poststructuralist orientation in semiotics would be more concerned with refining and critically analyzing the stories that structuralist semioticians construct—stories that purport to describe and explain the structures of other stories. Poststructuralist criticism is concerned with the extent to which analyses of narrative constructions are caught up in the processes and mechanisms they are analyzing. Poststructuralists are thus

suspicious of the view that anyone can get “outside” a cultural discourse or practice to describe its underlying rules and norms. For example, an analysis of political structures in a society cannot situate itself outside of these same political structures because it will necessarily be caught up in the processes and forces it attempts to describe, and will itself involve a political move or stance. Therefore, one way to investigate political structures and forces is to analyze the analyst’s own stance and seek to determine how her or his analytical discourse is worked by the structures and forces it is analyzing.

Structuralist assumptions have influenced contemporary thinking in education in significant ways, although in many instances, they are not identified as such by those who endorse them implicitly through their prescriptions and actions. As Cherryholmes points out, structuralism is consistent with teaching for objectives, standardized assessment, quantitative empiricism, systematic instruction, scientific management, and bureaucratic rationality. Such consistencies might alarm many critical-reconceptualist curriculum scholars, but they should also provide them with sufficient grounds not to dismiss structuralism as a failed (or fossilized) philosophy. Structuralist assumptions are alive and well, but they are not necessarily dangerous; only if they remain unacknowledged might they also be immune to criticism.

## STRUGGLE FOR THE AMERICAN CURRICULUM, THE

---

In 1961, Lawrence Cremin published his landmark study, *The Transformation of the School: Progressivism in American Education, 1876–1957*, in which he identified a progressive education movement comprising an array of theorists and policy makers and asserted that it had a significant influence on public education until the movement’s rapid collapse after World War II. Twenty-five years later, Herbert Kliebard presented a compelling, meticulously detailed account that questioned the existence of a cohesive progressive education movement as well as the movement’s impact on U.S. education. In *The Struggle for the American Curriculum, 1893–1958*, which was revised in 1995 and 2004, Kliebard portrays this 65-year period as more about competing ideas and policies and less about a unified progressive approach to educational (and social) change. Rather than transformation, he suggests a battleground; rather than a movement, Kliebard highlights the role of interest groups with rather consistent and recognizable ideological positions, sometimes allying for the achievement of reforms but more often vying for control in the contested terrain that is the U.S. curriculum.

A least four such interest groups competed for supremacy in the determination of the curriculum. The first group, which held sway on curriculum matters during the late 19th and early 20th centuries, was the humanists. Such educators as William Torrey Harris and Charles Eliot sought to provide children with a common curriculum that stressed mental discipline and the powers of reasoning on the one hand and the best of Western cultural

heritage and academic (university-based) disciplines on the other.

Reacting to the humanists' approach were three other groups of reformers that sought to change what schools taught and how the curriculum was organized. Developmentalists or child-centered progressives such as G. Stanley Hall sought curriculum that was more allied with the child's presumed interests, needs, and ways of learning. Some adherents, such as William Heard Kilpatrick, believed that children should not be taught directly but instead should engage in projects that essentially linked their immediate experiences and interests with worthy living.

A second group consisted of social efficiency educators or scientific curriculum makers who were particularly concerned with creating a smoothly running society. Educators such as John Franklin Bobbitt, W. W. Charters, and David Snedden looked to the work of industrial efficiency experts such as Frederick Winslow Taylor to guide them in their quest to make the best use of resources and effort in school life. They sought to ascertain, with expanded testing and counseling, the expected futures of children and then differentiate the curriculum so that children would receive the kind of education that would best prepare (fit) them for their predicted life after school.

A third group of reformers, reacting to the humanists' position, took a social meliorist or social reconstructionist approach to curriculum work, whereby teachers and students would function as principal actors in the advance of progressive social change and social justice. Emphasizing the political character of curriculum choices, the primary question for George Counts and Harold Rugg was not whether to advocate for a social vision, but the nature and extent of one's advocacy. These educators sought to strongly and openly advocate elimination of inequality, poverty, and prejudice (and in the view of others, to impose and indoctrinate their beliefs and values).

At the same time, there loomed another voice in the debates about schooling—that of John Dewey. The renowned U.S. philosopher explicated his own views of schooling and helped establish the Laboratory School at the University of Chicago in 1896. Dewey did not fit neatly into any of the camps just described and instead sought to

reconstruct the arguments in ways that respected the best of Western culture and its academic disciplines, took student interest into account, approached issues of efficiency from a more long-term perspective, and promoted democratic living.

The significance of *The Struggle for the American Curriculum* lies in its convincing argument that there was no unitary progressive education movement and that groups of educators and others with strong convictions about what should be taught to whom have long advocated for different approaches to curriculum deliberation and development. The result, as Kliebard makes clear, has been “a loose, largely unarticulated, and not very tidy compromise.”

## SUBALTERN CURRICULUM STUDIES

---

In a recent essay written for a 7th-grade English class, my granddaughter Janelle, engaged the questions: Who Am I? Who Are You? Who Are They? Ironically, these are the very same questions that concern subaltern scholars and which guide the work of those concerned with issues of curriculum studies. In fact, the questions and subsequent discussion, especially in regard to the intersubjectivity and fluidity of identity are central to subaltern curriculum studies.

In a 2007 essay, William Pinar defined curriculum as the intellectual site where individuals

struggle to define themselves and the world. The struggle that Pinar refers to is autobiographical, institutional, and highly complex, with new generations facing transformed worlds often times hardly imagined by their predecessors. For scholars and members of subaltern communities, however, curriculum studies also takes on the enormous burden of physical, cultural, and intellectual domination that comprise part of the legacy of colonization and imperialist practices brought on by the European domination of the world.

Referring to the European conquest of Meso-America, Pilar Gonzalbo notes that the initial conquest was a military endeavor, but the consolidation of the conquests depended on the ability to establish and maintain cultural and intellectual hegemony over the natives. This meant the annihilation of the Indigenous, cultural, discursive, and symbolic categories, or more simply put, the substitution of Western worldviews for the decimated cultural categories of the indigenous. Stuart Hall articulates the dilemma of the conquered by noting that such individuals have no history, no place to return, no language, and little knowledge of ancestors.

*Subaltern* is a term that is used most often in the area of postcolonial studies. The term, which originated in the work of Antonio Gramsci, is used to describe those individuals in subordinate positions of power. The term was adapted by postcolonial scholars beginning with its use by the subaltern studies historians, including Ranajit Guha and Partha Chatterjee, who have produced over five volumes of essays of *Subaltern Studies*, examining all aspects of subalternity including cultural, political, historical, and sociological themes. In an essay entitled, "Unpacking My Library . . . Again," Homi Bhabha uses the term *subaltern* as he describes oppressed minority groups whose presence serves to define the majority group. Bhabha argues that subaltern social groups always have the power to undermine the positions of those in positions of power because the dominant culture reproduces itself on mistaken identities of the subaltern.

Identity is central to the work of subaltern scholars such as Bhabha, Hall, and Gayatri Spivak, who elaborate greatly on the complexities of attempting to engage it in the shadow of cultural ruptures of the past related to the European

Imperialism. These scholars are part of a group of scholars associated with postcolonial studies, which is where the term *subaltern* is most often employed. Spivak in a widely cited piece, "Can the Subaltern Speak?" laments on the fruitless attempt to articulate an "impossible no," to the hegemony of the "West" which she describes as permeating the very heart of the consciousness of the subaltern.

Indeed, curriculum scholars, both subaltern and Western, have often taken heed of the metanarratives that emerged with the advent of modernity. Bernardo Gallegos elaborates on the curriculum of domination within the context of New Mexico and the Southwest. One of the prevalent legacies of the West's dominion over the world was the rise of modernity, characterized by the emergence of the Western (or European) Universal Subject. This theme arises in many contexts and classrooms throughout the world in the contexts of discussions about difference: Individuals may look different but all humans want the same things. The problem with the idea of the "universal subject" is that it universalizes certain traits common to Western subjects and promotes the idea that this is what is normal.

Renato Rosaldo, in "Culture and Truth," engages this point in a profound way by his study of the Llongot tribesmen who cut off the heads of neighboring tribes as a grieving ritual. Rosaldo invites readers to examine what are perceived as universal taboos as culturally based ways of interpreting reality. When one of the Llongot tribesmen questions the dropping of bombs on innocent Japanese citizens by Westerners, the issue of cultural relevance comes to the fore!

Subaltern curriculum scholars may never recapture lost worldviews, obliterated ways of thinking, or ways of being of our genetic ancestors. Descendants of slaves, such as Genizaro Indians in the Southwest or African Americans, may have to learn to live with the fact that we are children of imperialism, the descendants of colonialism. Indeed Hall is correct when he laments that his ancestors prayed and paid homage to gods he will never know!

Thus, curriculum studies for the subaltern moves into a sort of uncharted territory with infinite theoretical options. This is a space where the exploration of self, culture, and community is

inextricably tied to a great cultural, discursive, and historical rupture that has left the subaltern, especially slave descendents, with little to rest identity and scholarship on. Gallegos in *Performing School in the Shadow of Imperialism: A Hybrid, (Coyote) Interpretation* captures the discursive quandary well. Lamenting on the dilemma of subaltern scholar, unable to write from a place that is not inextricably tied to imperialist metanarratives, he argues for a “Coyote” interpretative framework. In the Southwest, *Coyote* was an ethnic group comprised of the children of Genizaro Indian servants and slaves. The term however is more widely known in the context of indigenous “Coyote Tales” most often equating “Coyote” as the cunning trickster who will do whatever it takes to promote its survival. The subaltern curriculum studies scholar obliged to take on the role of “Coyote” employs whatever theoretical frameworks fit at any given time to perform whatever is necessary for their survival in academic minefields in which they exist.

## SUBJECT-CENTERED CURRICULUM

---

Throughout the 20th century, most curriculum specialists in the United States relied on three or four data sources for making curriculum decisions: the child, the society, learning processes, and subject matter. Although alternative curriculum development approaches or models have been advanced that relied on the first three sources, the subject areas have dominated school curriculum since the beginning of formal education in the United States. Subject-centered curriculum remains the most common type of curriculum organization in most states and in most local school districts today.

In subject-centered curricula, the subject matter itself serves as the organizing structure for what is studied and how it is studied. In its purest form, the curriculum for each subject-area is designed by subject-matter experts and is intended to be studied using subject-specific methods and tools of inquiry. Emphasis is on developing an understanding of the major facts, concepts, contexts, and processes specific to the subject. The curriculum focuses on the enduring ideas and practices from the subject area.

The subject-centered curriculum model can trace its genealogy back to medieval European universities. The Latin grammar schools of England were transplanted to colonial United States with their inherent subject-centered approach intact. Latin, Greek, and mathematics were the key subjects included in the curriculum of Latin grammar schools in the United States. Over time, the subjects considered important by society and schools have changed. For example, by 1894 when the Committee of Ten issued its report, models for secondary school curricula were proposed that did not include the study of Latin or Greek. Instead of classical languages, the study of modern languages, such as French or German, was suggested because of their commercial value to business. Even though the seven *Cardinal Principles of Secondary Education* were purposefully phrased to stimulate cross-subject thought and practice, they were unable to unseat the subject-centered curriculum from the secondary schools.

Even though the subject-centered curriculum has remained the dominant curriculum design in

U.S. schools, some changes in how subject areas are defined have occurred over time. For example, before the 1920s, history was a distinct and separate subject. Economics, geography, and political science were also their own distinct separate subjects. However, by the 1930s *social studies* had become the generally accepted term for the broad field of study including history, economics, geography, and political science. Although a new subject area—social studies—had emerged in an effort to help present a more coherent and integrated curriculum, history remained the dominant subject in the broad field.

The creation of subject-specific standards and an emphasis on standards-based curriculum have been the most recent developments in subject-centered curricula. Typically developed under the auspices of national or international subject-specific professional organizations, these standards attempt to codify the knowledge all K–12 schoolchildren should experience during their educational experience. The standards writing tradition began in the 1990s after the National Council of Teachers of Mathematics (NCTM) released its first edition of standards for K–12 mathematics education. The NCTM standards were quickly followed by standards in all other major school subjects, including English, social studies, science, physical education, fine arts education, and modern languages. Additionally, standards have been developed for life skills, information literacy, collaboration, and other supporting areas for learning.

After the release of standards by national professional organizations, many states began adopting or adapting them for use in state-mandated minimum-competency testing programs. All children educated in a state must sit for these examinations, so schools scrambled to align their local curricula to the state-national standards. As a result standards-based curriculum development and standards-based instruction have become the most common version of the subject-centered curriculum currently used in the United States. Resources have been developed to support classroom teachers, principals, and district subject-area specialists as they work to develop standards-aligned, subject-centered curriculum and lesson plans. The creation of standards by national organizations of subject-specialist teachers at the K–12

and university levels has resulted in a de facto national curriculum in the United States. The creation and general acceptance of these standards by state and local schools have reaffirmed the privileged position of the subject-centered curriculum in U.S. schools.

## SUBTRACTIVE EDUCATION

---

Subtractive education refers to curriculum policies, processes, or practices that remove students' culture or language from classroom contexts as a resource for learning or as a source of personal affirmation. Subtractive education assumes that students' academic successes depend on the degree to which they give up their own cultures or linguistic practices or traditions to assimilate into mainstream culture, a process often referred to as "Americanization" in the United States.

In her landmark book, *Subtractive Schooling*, Angela Valenzuela demonstrated that academic achievement is a social process that emerges through the lived experiences of students as they negotiate the numerous social, cultural, historical, and linguistic relationships that define their lives both in and out of school. Increasingly, public school curricula are organized in ways that systematically remove, or *subtract*, from the classroom context cultural resources for historically marginalized youth. The phenomenon of subtractive education leaves these students progressively vulnerable to academic failure because it denies them important social and cultural capital that

might otherwise assist them in establishing connections between themselves, curriculum content, and academic achievement. Thus, “the problem” of academic achievement among historically marginalized students can be found not with students, but with curriculum policies and practices that by design are intended to erase students’ culture.

One curriculum policy that has been widely associated with subtractive education practices includes external, high-stakes, standardized testing programs. Educational researchers who have focused their investigations on the effects of external testing systems on historically marginalized racial, cultural, or linguistic student groups have documented clearly the ways that such testing programs stand in stark contrast with cultural practices and even ways of understanding or gaining knowledge. Although judgments about historically marginalized students’ academic abilities or potential are made based on low test scores, many curriculum scholars have concluded that these scores merely reveal the degree to which these students have given up their own cultures and transitioned into mainstream, English-speaking, White culture. Other subtractive curriculum policies include English immersion, or English-only policies, as curriculum moves away from multicultural education toward canonical-focused curricula.

In contrast to culturally subtractive curriculum policies, culturally additive curriculum policies equalize educational opportunities by helping historically culturally or linguistically marginalized students to assimilate into the larger society through bi- or multicultural cultural processes. Through additive schooling policies, students do not have to choose between being, for example, Mexican or American; instead, they can be both. Whereas in a subtractive school setting, a student’s home culture and home language are viewed as deficits, or impediments to academic success, in additive educational settings, home culture and language are assets.

## SUMMERHILL

---

Summerhill, a pioneering experiment in progressive, democratic education founded in 1921 by A. S. Neill, is a coeducational boarding and day school located in Suffolk, England, directed today by Zoe Readhead, Neill’s daughter. Begun as part of an international school called the Neue Schule near Dresden, Germany, the school soon moved to a castle on top of a mountain near Sonntagsberg in Austria, and in 1923 to the town of Lyme Regis in the south of England, to a house called Summerhill. In 1927, the school moved to its present site at Leiston in Suffolk, keeping the cheerful name Summerhill. During World War II, the school community evacuated to Wales for a time so that the British Army could use the site as a training facility, returning after the war to a run-down place.

Summerhill school has been running continuously since 1921, and it has consistently adhered to its essential character and philosophy, which can be succinctly stated as the belief that the school should be made to fit the child, rather than the other way around, and that the function of the child is to live his or her own life—not the life that anxious parents think best, nor the life prescribed by authoritative and certified experts. Neill believed that play belongs to the child absolutely and that children ought to be free to play as much as they like. Creative and imaginative play is an essential and entirely natural part of childhood, he argued, and spontaneous play could only be

undermined if adults tried to channel it toward “learning experiences.”

The philosophy and practice of Summerhill explains in part all the early relocations: affiliated educators and especially neighbors found the school radical and a bit nuts. Neill himself was a commanding figure—tall, opinionated, a severe Calvinist in upbringing and bearing—and he courted controversy. To underline his idea of freedom for children, he told stories, for example, of coming upon a group of boys throwing rocks at the schoolhouse windows, and rather than reprimanding or punishing, joining in the activity.

The school was depicted in the British press as the “Do-As-You-Please-School,” but over time won the respect of many well-known educators, artists, authors, and social scientists, including Bertrand Russell, Margaret Mead, and Henry Miller.

In the 1960s, Neill was approached by Harold Hart, a publisher from the United States, who wanted to publish a compilation of Neill’s writings. The result was the book *Summerhill: A Radical Approach to Childhood*, an instant hit that became number one on the nonfiction best-selling list. It was soon published in England and many other countries becoming an international sensation and putting Neill and Summerhill on the map as leaders in alternative and progressive education.

*Summerhill* with its message of love and peace and freedom combined with its sharp critique of authoritarianism of any kind, hierarchy, control, sexual repression, shame, and punishment, hit the American *zeitgeist* like a divinely guided missile. It became a required text in the blossoming counter-culture, and both inspiration and road-map to a generation of teachers and education writers. John Holt, Herb Kohl, Jonathan Kozol, Paul Goodman, Bob Davis, and George Dennison all reported important encounters with Neill’s book.

Summerhill is still run as a democratic community with the business of the school conducted in school meetings, which serve as both the legislative and judicial body. Anyone, staff or pupil, may attend meetings, and everyone, from the youngest child to the head of school, has an equal vote. Members of the community are expected to make the decisions that affect their lives—a radical

notion of participatory democracy in practice—and are free to do as they please, as long as their actions do not cause harm to others. This extends to the freedom for pupils to choose which lessons, if any, to attend. All of this is the embodiment of Neill’s guiding principle: freedom, not license.

## SUPERVISION AS A FIELD OF STUDY

---

Supervision as a field of study is complicated for a number of reasons. Perhaps the most important of these reasons is that a deep division exists within the field about whether the purpose of supervision is to provide administrative oversight or to support teachers’ instruction. Another reason is that scholarship having to do with supervision does not exist as a well-demarcated body of literature and research, but can often be found within other related educational fields, including curriculum. Yet another reason is that supervision, both as a practice as well as a field of study, extends across the full range of a teaching career, and assumes various forms to address the needs and interests of teachers at varying stages of their professional development. Nevertheless, because specific models of supervision have been developed and widely researched, and because supervision is an important aspect of many roles in educational settings, it warrants consideration as a field of study.

### The Purpose of Supervision

History appears to be the best explanation for the schism that has developed in the field of

supervision between what can be described as its administrative and its instructional support purposes. The administrative purpose derives from monitoring and inspection practices recognized as formal supervisory responsibilities in the United States since the earliest schools in the original colonies. Beginning with committees of selectmen who visited those schools to make sure that teachers were living up to community expectations, to the inspection of schools in the country's growing cities by superintendents and later—as school systems grew larger—by principals and district central-office personnel, administrative oversight has existed to ensure the quality of teaching. The goal of such oversight has been to assess the quality of the teaching at any given time and, as Daniel and Laurel Tanner point out, has since colonial times also had improvement of instruction as an important goal.

For administrative supervision, such improvement of instruction is best addressed at a systems level. Good instruction at the classroom level depends on having high-quality components in other parts of the school or district system. An example of such a systems component is a formal curriculum aligned for scope and sequence across grades and subject areas, and perhaps even requiring teachers to implement prescribed lessons. The administrative supervisor's role is one of monitoring that this curriculum is being implemented in classrooms. Another example of the systems approach that characterizes administrative supervision is the use of a teacher evaluation of observation checklist to note the presence or absence of specific teaching behaviors. The administrative supervisor uses this checklist as the basis for an assessment of teachers' competence against the standard implicit in the checklist items.

The Hunter model that was widely used in the 1970s and 1980s provides a good illustration of administrative supervision. In that model, a seven-step lesson design sequence is accompanied by a checklist that administrators use during classroom observations to document the use of each of the steps. The model reflects a tightly integrated bureaucratic structure of clearly defined systems of instructional design, teaching, and evaluation.

Conversely, supervision for the purpose of instructional support approaches the goal of improving instruction from the perspective that

supervision offers teachers the assistance they need to become better practitioners. As such, it is an outgrowth of the development of teacher education programs in normal schools and in some city school districts during the late 19th and early 20th centuries. In contrast with administrative supervision, which assumes that well-designed and monitored systems are sufficient to ensure good teaching, supervision as instructional support assumes that teachers develop their knowledge and skill through the experience of teaching. Furthermore, teachers are thought to develop such knowledge and skill in more individualistic and idiosyncratic ways.

Supervision as instructional support focuses on individual teachers or on small groups of teachers. Supervisors' work is close to the classroom as they collaborate with teachers to plan instruction and to review with them the evidence of the teaching and the students' learning that occurs in their particular classrooms. The role of the supervisor is to serve as a resource and an experienced colleague responsible for helping teachers become more aware of their own values about teaching and to assist them in building on their strengths and overcoming their weaknesses as practitioners.

Donald Schön's theory of reflective practice has offered a strong foundation for supervision as instructional support for the last three decades. Noreen Garman has called such reflection the heart of supervision. The roots of reflective practice lie in John Dewey's notion that experience is the basis for learning. In the case of supervision, reflective practice takes place at two levels. The first are teachers' deliberations with the supervisor about their teaching experience to develop or deepen their understanding of that experience—what Schön called *reflection-on-action*. The second—*reflection-in-action*—takes place as teachers are empowered in the supervisory relationship to become more aware during the actual process of teaching of their use of improvisation and intuition to achieve their instructional goals, and to value their use as a means for creating new knowledge and understanding of their practice.

### Supervision and Related Educational Fields of Study

Although supervision is recognized as a field of study in its own right, the fact that material on

supervision can also be found in the literature of a number of related fields blurs the boundaries distinguishing supervision from those other fields. For example, supervision is recognized in the field of educational administration as a function of administrative leadership. The administrative role most often identified with supervision is that of the principal. This identification is found both in literature and in practice where teachers view their principal as their supervisor. Particularly in these times of heightened accountability, principals are expected to assume the supervisory responsibilities associated with improving instruction in their schools. Those responsibilities include overseeing the work of teachers, and monitoring its quality as well as the results produced in the form of student learning.

The supervisory function that is most identified with administration, is the evaluation of teaching that, in most schools, principals are required to perform. Although the 2001 No Child Left Behind legislation emphasized student test data as an indicator of teachers' effectiveness, the formal evaluation process that includes classroom observation by an administrator and a summative postobservation conference remains the major official supervisory responsibility of principals. Patricia Holland and Noreen Garman, in fact, have argued that legislative mandates in most states for such observation-based evaluation of teaching are what give supervision its formal legitimacy as a practice.

Supervision also overlaps with the field of curriculum. The founding of ASCD in 1943 recognized the close relationship that had developed between supervision and curriculum, a relationship in which supervision ensured that teachers understood the curriculum and were implementing it successfully. Supervision meant the supervision of curriculum and was the responsibility of district-level curriculum coordinators. Their knowledge of supervision was intertwined with that of curriculum. By the early 1990s, however, there had developed what Edmund Short refers to as an estrangement between supervision and curriculum in which supervisors often had limited knowledge of curriculum and focused instead on technical skills of teaching. The implications of this estrangement were even more apparent in scholarship in the two fields as supervision became

increasing associated with more technical, administrative issues, and curriculum studies became more theoretical.

Another field that shares common ground with supervision is teacher education. In this field, the support function of supervision is most obvious, not surprisingly given that a major context of supervision is the supervision of preservice teachers, most often in their student teaching settings. This practice of preservice supervision focuses on how supervisors and cooperating teachers can best help aspiring teachers develop their understanding of and skill in teaching. During the past two decades, the theory of reflective practice has been widely adopted in the field of teacher education as foundational to teacher preparation programs and to the ways in which university supervisors of student teachers perform their role. Reflective practice was described earlier as also informing the study and practice of supervision. As such, this theory has forged the connection between supervision and teacher education scholarship in recent years.

A vibrant body of scholarship has also developed in teacher education around the professional development of teachers during their teaching careers. This scholarship is often distressing to scholars of supervision who contend that it fails to reference related work and concepts that have long been addressed in supervision. Action research, for example, is widely discussed in the literature on teachers' professional development, and has also been promoted by Carl Glickman and others as an important strategy in supervision. The failure to explicitly connect teacher professional development and supervision has diverted attention from the support function of supervision as scholars with an interest in this function have come to identify not with supervision, but with teacher professional development, which has become its own field of study.

### Supervision Throughout a Teacher's Career

Supervision occurs in various forms throughout a teacher's career. From the preservice supervision of student teaching through what Frances Schoonmaker described as approaches that encourage the renewal of veteran teachers' engagement in their practice, different forms of supervision exist

to address the needs and interests of teachers during their teaching career.

A hallmark of current in-school supervision is that teachers themselves assume responsibility for their own professional development as well as that of their colleagues. One such form of supervision that has become increasingly central in recent years with the growth of alternative certification programs for teachers is the mentoring of novice teachers by their more experienced colleagues. Teachers also assume collegial responsibility in other forms of in-school supervision such as peer coaching among veteran teachers, the use of “critical friends” protocols by groups of teachers, action research by individual teachers or small groups with a shared interest, and the “trainer of trainers” model in which certain teachers receive extensive preparation in a particular area or innovation so that they may assume a role as a resource for other teachers.

Diversity among the forms of supervision coupled with the diversity among teachers in their professional development needs and interests contributes to the complicated nature of inservice supervision as a field of study and practice. The development of standards for in-school supervision programs is a recent attempt to provide these programs with a cohesive identity as components of a school’s supervision system.

### Models of Supervision

Two widely researched and referenced models of supervision have shaped supervision as a field of study and practice during the past several decades. The first of these is clinical supervision, which was developed by Morris Cogan and his colleagues in Harvard’s master of arts in teaching program over a period of years beginning in the mid-1950s. The model—or “rationale” as Cogan called it—for clinical supervision rests on the premises that supervision is a process that occurred between colleagues, and that it involves the close examination of particularly chosen aspects of teaching and learning as they occur in a teacher’s classroom. A supervisor and a classroom teacher determine in advance what the focus of supervision will be and what evidence can be obtained during classroom observation to inform their study of that focus, and then meet together to analyze the evidence.

The goal of this process is to help teachers understand their practice better and to afford feedback and support they need to develop skills in the “clinic” of the classroom. Cogan articulated this process in eight specific steps or “phases” that included the supervisor and teacher working together to plan the lessons that would be observed and analyzed. Other supervision scholars have placed greater emphasis on the observation and postobservation conference, and less on collaborative planning. However, the core of clinical supervision as a process of classroom observation and analysis has become recognized as the way supervision is practiced.

The other dominant model of supervision is developmental supervision. Initially described by Glickman, this model draws on human development theory to explain three basic approaches to supervision that are appropriate for teachers at varying levels in their professional knowledge and skill. A teacher’s level of development is determined by two variables: commitment to students and to the work of teaching, and abstraction, which is the ability to think conceptually about teaching and classroom problems and to identify alternative approaches to practice. These two variables correspond to three approaches of directive, collaborative, and nondirective supervision that exist along a developmental continuum. The assumption is that as teachers mature professionally, their levels of commitment and abstraction increase, and they progress along the continuum. It is the supervisor’s responsibility to identify the teacher’s developmental level and to employ supervisory strategies that are appropriate to that level.

Clinical and developmental supervision are not mutually exclusive, but can be used concurrently for classroom supervision. Developmental supervision, however, also extends beyond the classroom to include a broader range of opportunities for teachers’ professional growth, such as curriculum development, staff development, and action research.

The two models of clinical and developmental supervision have been used as contexts for the study of supervision as it occurs in practice. Studies that view supervision from both administrative and support perspectives have adopted clinical and developmental supervision as models to define the practice of supervision. As such, these two models

have shaped a stable conceptualization of supervision as a field of practice and study.

more fully understanding attitudes of participants regarding a topic of interest. Unlike experimental studies, survey studies attempt to avoid interventions with participants so as to capture reality as it exists at a given point in time. Survey research is important in the field of curriculum studies and is adaptable across a wide range of research problems. For example, survey data can be useful in understanding attitudes of educators, students, and others regarding new curricula, teaching practices, and curricular reforms.

Surveys may include collection of quantitative, qualitative, or mixed mode data, and data may be collected directly (e.g., via interview) or indirectly (e.g., via mail) from either individuals or groups. Highly sensitive topics (e.g., participant involvement in illegal activities) are often best addressed using indirect anonymous surveying methods. Survey data collection typically requires three elements: a survey tool (items), a sample of respondents (informants), and an interviewer. If surveys are administered indirectly (e.g., via mail, e-mail, or a Web site), no interviewer is needed. Careful development of survey tools is essential. Survey items may be open- or closed-ended depending on the type of responses sought. Items should be written to evoke the type of responses desired without being too leading. Moreover, care should be taken to sequence the questions so that more positive, higher-interest items come before negative or more tedious questions. It is also important to keep a written questionnaire or interview to a reasonable length to avoid participants' loss of interest or failure to complete the survey.

Surveys may be administered in a variety of ways. Direct methods, such as personally administered pencil and paper surveys, face-to-face interviews, and telephone polling, provide the researcher with opportunities for personal interaction with the participants as well as the ability to ask clarifying follow-up questions and to identify problems with administration of the survey. Focus groups allow the researcher to assess the views of a number of participants simultaneously, and the social interaction provided in this setting may increase the quality of the data gathered. Advances in technology during the last two decades have yielded new methods (e.g., personal response system "clickers") for gathering numeric data from a live group of participants. Indirect methods (e.g., mail,

---

## SURVEY RESEARCH

---

The term *survey research* refers to a family of non-experimental research methods using the collection of self-report data to assist the researcher in

e-mail, Internet surveys) allow surveys to be distributed to large samples at a relatively low cost; however, response rates tend to be low (often around 20%), some respondents fail to answer all of the questions, and it is difficult to determine who is actually responding to the surveys and whether there are problems with survey administration. When response rates are low, follow-up reminders can sometimes prompt nonrespondents to complete mail or Internet surveys.

Surveys may be used to provide descriptive data relative to a phenomenon of interest or to investigate relationships between variables. Survey data lend themselves to a variety of research designs and data analytic procedures depending of the type of questions asked. Continuous response formats (e.g., Likert scales, semantic differentials) generate numeric data that can be compiled and summarized in a variety of ways using descriptive statistics. Cross-tabulations may be used to compare survey responses across demographic subsets and allow the researcher, if desired, to test causal comparative or correlational inferences. Interviews and free-response written questions yield verbal data that can be subjected to content analysis or coded for use in ethnographic or grounded theory studies.

Careful selection of a sample is important to the success of survey studies. Samples may be selected using probability (e.g., random, stratified random) or nonprobability (e.g., convenience, snowball) methods. Regardless of the sampling method employed, the researcher should clarify the population of interest to which generalizations are sought and provide adequate description to show how the sample in hand represents the heterogeneity of that population. Whereas most survey studies involve small samples or research problems of a local scope, there are examples of large national surveys of curriculum. For example, the ACT National Curriculum Survey collects data from a nationally representative sample of several thousand educators every 3 to 5 years to determine the skills typically taught in reading, mathematics, English/writing, and reading at the middle school, high school, and college levels. The survey also determines educators' attitudes about the preparedness of students for college-level work.

## SYNOPTIC TEXTBOOKS

---

Synoptic textbooks were developed to summarize and conceptualize curriculum literature for curriculum leaders and burgeoning scholars as it began to expand and differentiate during the first half of the 20th century. The term *synoptic text* in curriculum literature was first used in 1980 by William H. Schubert and Ann Lopez Schubert in *Curriculum Books: The First Eighty Years*. Application of the term to curriculum studies derives from the theological labeling of the Christian Bible's New Testament gospels (Matthew, Mark, and Luke) as synoptic because they provide synopses of the life of Jesus Christ. Historically, another source called *Q* has not been located, but is believed to contain many direct quotations of Christ. Metaphoric use of *synoptic* in curriculum studies then sees *synoptic curriculum textbooks* as summaries of central contributions in the *life* of the curriculum field, and collections of primary source articles as equivalent to *Q*. Although it might seem out of place to use such a religious analogy, the contention fits with the seriousness of theorizing about what children and youths need to know to live good and just lives. This is the essence of the question (What is worthwhile?) that lies at the heart of curriculum inquiry. James B. Macdonald is often quoted for capturing the seriousness of curriculum theory as a prayerful act.

The first widely recognized synoptic curriculum text was *Curriculum Development* by Hollis Caswell and Doak Campbell, published in 1935. Early synoptic texts often used the term *curriculum*

*development* in the title. This is indicative of the curriculum development era as distinguished from the era, begun in the 1970s, that has become known as the curriculum studies era. The latter placed focus on *understanding* curriculum in schools and other educational dimensions of society rather than on merely *developing* preordained learning experience in schools. These two curriculum eras were principally distinguished by William Pinar and colleagues.

Several curriculum texts preceded those by Caswell and Campbell (e.g., by Franklin Bobbitt, W. W. Charters, Henry Harap, and L. Thomas Hopkins), but they were designed to be guidebooks for curriculum leaders in schools, more than synoptic conceptualizations of the literature. Only Hopkins's 1929 *Curriculum Principles and Practices* moved beyond the how-to manual approach, by engaging readers in philosophical underpinnings of questions that perplexed practitioners. This creative variation of synoptic questioning had precedent in the *26th Yearbook of the National Society for the Study of Education*. Constructed by an all-star team of curriculum scholars from different intellectual persuasions and led by Harold Rugg, this volume resulted in a composite statement, and comments of rebuttal by members of the team. Despite the indelible contribution of Rugg's 1927 committee, the Caswell and Campbell effort was the first to attempt to organize knowledge of the field as a basis for curriculum development. Thus, it is deemed the first synoptic curriculum textbook.

The synoptic text was considered to be a scholarly achievement in its own right, since it was at once a review of the literature and a reorganization of salient ideas of the field. For at least seven decades, synoptic textbooks set the stage for curriculum scholarship and leadership, especially during the curriculum development era. Dominant synoptic texts of the 1940s were authored by J. Minor Gwynn in 1943, who published editions across four decades, and was joined in the late 1960s by J. B. Chase; Harold Albery, in 1947 who was joined by Elsie Albery in subsequent editions; by Florence Stratemeyer and coauthors H. L. Forkner, M. G. McKim, in 1947, joined by A. H. Passow in a 1957 edition.

A key synoptic curriculum text of the 1950s was authored by B. Othanel Smith, William O.

Stanley, and J. Harlan Shores, titled *Fundamentals of Curriculum Development*. The 1950s also brought a more streamlined kind of synoptic text, *Basic Principles of Curriculum and Instruction* by Ralph Tyler, first published in 1949, with many subsequent printings. It was an analytical frame constructed around four central questions or topics: purposes, learning experiences, organization, and evaluation. These factors became the organizing structure of lesson plans, instructor's manuals for textbooks, units of study, whole curricula, and the influence was worldwide. Tyler's topical questions emerged from his experience as director of evaluation on the Eight Year Study, and one of his key associates in that work, Hilda Taba, authored the major synoptic curriculum text of the 1960s, *Curriculum Development: Theory and Practice*, published in 1962. Like the Smith, Stanley, and Shores's texts, Taba's brought a substantial array of literature together to conceptualize major considerations of curriculum scholarship and practical enactment.

Two books exemplify the *Q* emphasis on primary sources by bringing together readings from journals that could supplement the secondary sources that synoptic texts provided: M. D. Alcorn and J. M. Linley's *Issues in Curriculum Development* in 1959, and E. C. Short and G. D. Marconni's *Contemporary Thought in Public School Curriculum* in 1968. As the field moved away from exclusive preoccupation with curriculum development in the 1970s, the last major synoptic text espousing curriculum development was produced in 1975, *Curriculum Development: Theory Into Practice* by Daniel and Laurel Tanner, a book that emphasized curriculum history more than any of the preceding synoptic texts, and brought out new editions for three more decades.

In addition to synoptic curriculum texts that established new integrations of curriculum to guide scholarship, another useful brand of synoptic text emerged over the years, one that addressed practical concerns of teachers and school leaders. Descendants of early books by Bobbitt, Charters, Harap, J. K. and M. A. Norton in 1935 and L. M. and D. M. Lee in 1940 and 1950—two of the best known of these practice-oriented texts were authored by J. Galen Saylor and William M. Alexander (both former students of Caswell). A text first published in 1964 with revisions through

four decades by Ronald C. Doll combined synopses of literature with how-to approaches. Other volumes bridged the gap between the scholarly synoptic texts and the practitioner-oriented ones, such as those by Gerald R. Firth and R. D. Kimpston in 1973, and Ronald Zais in 1976. Today, the tradition of synoptic texts for practitioners continues with books by many authors, often in several editions, for example: J. Wiles and J. Bondi, P. Oliva, A. Ornstein and F. Hunkins, G. Posner, and A. Rudnitsky, and additional texts that bridged the scholar-practitioner gap, such as those by Colin Marsh and George Willis, Decker Walker, and by George Posner.

During the postcurriculum development era, new variations of the synoptic text emerged to characterize the new field of curriculum studies. One of the first attempts was by Elliot Eisner starting in 1979, with subsequent editions, that focused on imaginative and artistic dimensions of curriculum design and evaluation that drew upon images of critics and connoisseurs applied to education. Another kind of synoptic text by Schubert combined perspectives from the educational foundations with paradigms to express possibilities that integrate concerns of both developing and understanding curriculum. Bibliographical studies were offered as another synoptic text under the assumption that synopsis should consist of listing curriculum books, placing them in context, and discussing themes of thought in each decade, such as provided by Schubert and Lopez Schubert in 1980, and augmented by Schubert, Lopez Schubert, T. P. Thomas, and W. M. Carroll in 2002. Another variation of synoptic text was provided in 1995 by Pinar, William Reynolds, Patrick Slattery, and Peter Taubman, one that organized curriculum relative to several discourse communities: historical, political, racial, gender, phenomenological, postmodern, biographical or autobiographical, aesthetic, theological, international, and institutional texts—the latter being focused on curriculum development, teachers, and students in schools. Dan Marshall, Jim Sears, and Schubert provided a postmodern pastiche-like synoptic text in 2000 that was revised in 2007 with new third and fourth authors, Louise Allen and Patrick Roberts; it consisted of a chronology of selected excerpts since 1950, commentaries from interviews with major scholars in each era, parallel stories from cultural

developments, commentaries by the authors about curriculum work done during each era since 1950, and extensive bibliographies.

Today, the notion of synoptic can be seen as central to curriculum itself, raising the question of how human beings learn from what has gone on before, incorporate it to understand the present, and use it to forge possibilities for their futures. As well, synoptic perspectives pertain to ways in which educators in schools have summarized that which is deemed worthy of knowing, often struggling with prevailing societal demands of government and business and grappling with the interests served. Perhaps the future of synoptic work will focus more on questions to be raised than on answers to be purveyed.

## SYSTEMIC REFORM

---

The contemporary education policy period marks a shift away from the idea that change happens

organically, one school at a time. Instead, there is a focus on creating a systematic infrastructure to support change, and the goal is to achieve change across a large number of schools at the same time. In recent decades, there have been several types of systemic reform efforts in the United States and across other Western countries, most significantly the growth of state and federal systems of standards and accountability.

The publication of the 1983 report, *A Nation at Risk*, likely marked the beginning of the systemic reform movement in the United States. The report argued that students in U.S. schools failed to compete on an international level and lagged behind in several key foundational areas. Although some criticized the report for being overly alarmist and inaccurate, most agree that the report prompted policy makers to question the value of public education in terms of its effectiveness and outcomes given the past two decades of increased investment. Soon thereafter, the standards-based reform period then entered the policy stage of the mid-1980s and 1990s.

Following the recommendations made by the report, policy aims turned to improving the academic and professional quality of U.S. schools. Policies focused on establishing minimum competency standards targeted at students and teachers. More specifically, the recommendations focused on raising high school curriculum and teacher education standards. The main policies included increasing academic standards, adding teacher credentialing requirements, and intensifying school-related practices (e.g., increasing school hours).

However, most state systems lacked coherence in their overall approach to reform. Thus, although the underlying hope of the federal policy initiatives were to improve teacher and student performance, the policy designs focused on fidelity and establishment of programs rather than on the quality of programs. As the standards-based reform era developed momentum, the policies of the 1990s explicitly focused on improving the quality and delivery of school-related services, especially instruction and curricula. Making a strong case against piecemeal approaches to reform, Marshall Smith and Jennifer O'Day, in a now-landmark article, argued for system alignment and coherence. Policy instruments were developed to produce systems-level reform by emphasizing alignment

of resources, coordinating efforts amongst government agencies, and redistributing authority. During this period, new governance structures such as site-based management and charter schools took stage. Redistribution of authority, comprehensive school reform models, and public-private partnerships also emerged as important features of the reform landscape.

The crystallization of systemic reform movement occurred with the No Child Left Behind Act (NCLB) of 2001, which instituted the first federal accountability system based on assessments and standards. As the reauthorization of the Elementary and Secondary Education Act (ESEA), NCLB is particularly noteworthy because it moves past the traditional focus on schooling "inputs" and holds educators responsible for student performance results. Under this system, the mechanisms for accomplishing these goals emphasize data-driven decision making, the implementation of evidence-based practices, and increased school choice for parents. Specifically, it requires states to have standards detailing content for student learning. Testing is also mandatory for Grades 3 to 8 and results must be used to drive instruction and teaching practices. In addition, student performance data must be disaggregated based on major demographic classifications such as race/ethnicity, socioeconomic status, gender, disability, and English language learner status. The accountability demands were coupled with prescriptive intervention remedies for schools not meeting adequate yearly progress (AYP). Schools are pushed to improve under threat of sanctions that ultimately allow parents to opt out of low-performing schools. Additionally, guidelines for enhancing teacher quality were laid out.

Thus, the systemic reform movement marks a shift in policy making from the reliance on resources, incentives, and compliance to the current reform trinity of standards, assessments, and accountability. These new policy tools are held together by assumptions on the need for policy coherence, system alignment, and coordination among various education agencies. Standards, tests aligned to standards, and accountability systems are stronger policy instruments because they attempt to directly influence instruction and student outcomes. However, the how and why of teaching and learning remain unaddressed.

Standards provide guidance on classroom content but do not necessarily assist teachers in translating standards into effective instructional practices.

Nevertheless, with the aim of improving the effectiveness of schooling practices and a focus on student outcomes, the scale of its intended impact has led to increased centralization and standardization across all levels of the system.

## TABA, HILDA

---

Hilda Taba (1902–1967) struggled to find the most effective way to create curriculum that would yield what she considered to be an educated populace; critical thinkers searching for meaning and understanding of the world around them and prepared to meet the challenges of a future that would be constantly changing. This struggle was not a top-down, externally created, and imposed curriculum package, but rather a process of developing curriculum from the bottom up by working with the classroom teachers delivering that curriculum to their students using instructional strategies that would further the goals of education in a democratic society. Taba's principles of curriculum can be easily implemented in any academic discipline or across disciplines as desired by the local school system. Taba's interests in the integration of objectives in the areas of content, skills, and attitudes as well as her inductive instructional strategies—concept attainment and concept development—to realize those objectives would be considered cutting-edge pedagogy today. Her concerns with what in her day was called “intergroup education,” currently known as multicultural education, as well as her interest in instructional strategies focused on minority, in those days, “culturally disadvantaged,” or diverse students makes her an educator whose ideas are timely. Her interests in action research, in evaluation as crucial to the educational process and her belief that there is a need for qualitative as well as quantitative measurement in

that evaluation process, reinforce the timeliness of her ideas as a curriculum theorist. For Taba, learning to think was the main goal, and balancing the curriculum to meet multiple needs was the path to attainment of the goal.

In 1935, Taba was invited by Ralph Tyler to join the Eight Year Study where she was put in charge of the team evaluating social sensitivity, a topic related to the goal of preparing students for effective democratic participation. This is an area not easily assessed by traditional pencil and paper tests because it concerns attitudes about class, race, and ethnicity generally seen in students' social lives rather than in academic preparation. Thus, the evaluation would need qualitative as well as quantitative measures.

As a result of this experience, a crucial part of any Taba curriculum plan became staff development—working intensively, often in workshops, with teachers to assist them in understanding the concepts, ideas, and pedagogy necessary to implement the curriculum. Significantly, the first step was for the teachers to identify problems they were having in their classrooms with the curriculum or student learning. Everything flowed from the felt problems of the teachers with curriculum changes coming afterward as part of the solution to the teachers' problems. Taba believed that until teachers understood their curriculum—what they were doing and why they were doing it—no really effective student learning could take place. In other words, deep teacher understanding promotes student learning.

In 1944, as director of the Intergroup Education in Cooperating Schools project, Taba called for

educators to develop their students' empathy toward diverse cultural perspectives while placing great emphasis on the power of critical intelligence and common—democratic values in the fight against bigotry. Units of study would vary according to the needs of the students but the objective of prejudice reduction would remain constant. In many respects, this is an action research approach. The teachers identify felt problems with their own situations—classroom, curricula, student learning, school, community—and seek to solve the problems. The evaluation of the success of the solutions—new curriculum or pedagogy—required new evaluation methods, similar to those in the social sensitivity study where qualitative changes in attitudes as well as accumulation of academic knowledge and skills were the ultimate goals.

Taba's next big projects were to engage in a long-term curriculum project revision with the K–8 social studies teachers in Contra Costa County, California, and to publish her synoptic text on curriculum development. These reflected Taba's core ideas: content needs to be sampled, and, although the concepts may be generalizable to a "standardized" curriculum, even a national curriculum, the specific content examples or "samples" would vary from school to school and even, depending on the learners' needs, from classroom to classroom. Further, once fundamental concepts are decided upon, they need to be taught at higher and higher levels of abstraction across the years of schooling. The best demonstration of this "spiral curriculum" is the curriculum developed by the teachers in Contra Costa County. Once the concepts, generalizations, and units of study had been determined, the students' learning experiences or activities would be decided upon by the teacher(s).

Taba firmly believed that each learning activity required pedagogy appropriate to the achievement of the generalization that students were supposed to acquire. In almost every case, the pedagogy of choice was active and inductive. The testing or evaluation of this curriculum would be focused on the ability to use the understandings, that is, skills, knowledge, and attitudes in ways consistent with today's construct of authentic assessment tasks. Using the Taba process of moving from the specific to the general, the curriculum model begins with the stakeholders struggling over what objectives, concepts, skills, and attitudes are important to

include, and once the generalizations embedded in those concepts are formulated, teachers can design curriculum experiences, that is, learning activities, that enable the acquisition of that knowledge.

In our current top-down, standards-driven society, the Taba model gets little attention. Taba's insistence on teaching for meaning and understanding, learning for depth of knowledge, and inclusion of skills and attitudes important for life in a democratic society could use much more attention by curriculum developers and designers. Her belief in the importance of ongoing evaluation and curriculum refinement based on the results of the assessment data gathered has great salience in our accountability-driven age. Taba embodies the best of progressive educational philosophy while seeking rigorous inclusion of academic content. In the final analysis, Taba is about balance—integrating curriculum to create critical thinkers and problem solvers by using conceptual content and inductive pedagogies to prepare students for an active, fulfilling life. Taba's untimely death in 1967 cut off her longitudinal work with the Contra Costa teachers, but her curriculum model could be revived and implemented today if there were sufficient time and energy committed to staff development and funds allocated to implement the work.

## TACIT KNOWLEDGE

---

The concept of tacit knowledge is sometimes presented as a type of knowing with two dimensions: It is acquired through experience rather than

direct instruction, and the knower is unable to articulate it or, as the now familiar phrase goes, “We know more than we can tell.” However, a broader importance of the concept must be recognized because it represents a historic rupture in many social scientists’ understanding of the nature of knowledge. Developed by chemist and philosopher Michael Polanyi, the concept contributed to what has been called the “interpretive turn” in the social sciences, as well as to the reconceptualization of curriculum studies.

In the mid- to late 20th century, some social scientists began a shift away from positivism, the belief that there can be any scientifically neutral, impersonal perspective, and toward interpretivism, the belief that all human endeavors, including the scientific, are unavoidably embedded in cultural traditions and prejudices. Polanyi was one of the early voices protesting the notion of the possibility of detached objectivity. His work, arguing that all knowledge is based in tacit or “personal” knowledge, provided fertile ground for early reconceptualist theorizing. A look at the 1975 classic *Curriculum Theorizing: The Reconceptualists*, edited by William Pinar, shows that seven of the chapters draw on Polanyi’s theory of knowledge. Although Polanyi is only occasionally cited in current curriculum studies literature, his ideas helped make much of it possible, including, but not limited to, discourses based on the political (e.g., the hidden curriculum), the aesthetic, the spiritual, hermeneutics, autobiography, and narrative. Some of the most explicit development of the implications of tacit knowing for curriculum work can be seen in James Macdonald’s political work, as well as in his transcendental developmental ideology, and in Michael Connelly and D. Jean Clandinin’s work on personal practical knowledge.

Polanyi illustrated tacit knowing as a triad: First, there are the subsidiaries (e.g., senses) we employ in focusing on the second element: the object of our attention. The knower is the third necessary factor, for the individual integrates the subsidiary and the focal in the active process of tacit knowing. Polanyi emphasized that the tacit knowledge of any person or scientific community provided a matrix within which all inquiry occurs. As such, it supplies taken-for-granted assumptions, rules of evidence and procedure, and a sense of what is appropriate or inappropriate to investigate.

He found the ideal of a strictly explicit knowledge to be self-contradictory, noting that if all words, formulae, and graphics were stripped of their tacit properties, they would be meaningless. Therefore, because all knowing requires the knower’s continual integration of even explicit knowledge into the tacit, Polanyi concluded that all knowing is personal knowing.

## TAXONOMIES OF OBJECTIVES AND LEARNING

---

An objective can be defined as a statement of what educators intend students to learn as a result of the educational experiences in which educators engage students. Because objectives are statements, they take on a common form, namely, subject-verb-object. The subject is the learner or, more generally, the student. The object indicates the content to be learned. The verb indicates how the student is expected to process the content. Using this form, one objective might be, “The student will learn to classify poems.” In this example, the content is poems; the process is classify. The phrase “will learn to” is simply a reminder that intentions are involved, which, one hopes, will be actualized at some time in the future. Learners can learn to classify content other than poems. They can learn to classify animals, works of art, and numbers.

Benjamin S. Bloom was one of the first educators to realize the universality of a finite number of verbs across a variety of subject matters. Somewhat unfortunately, but understandable in the context of the times, he referred to these verbs as “student behaviors.” What came to be known as Bloom’s Taxonomy was, in fact, a classification of these universal behaviors.

Since the publication of Bloom’s Taxonomy in 1956, at least 19 alternate frameworks for classifying educational objectives have been developed. Eleven of these frameworks included a single dimension, as did Bloom’s Taxonomy. The other frameworks contained multiple dimensions, ranging from two through five. In November 1995, a group of eight cognitive psychologists, curriculum theorists, and instructional researchers, and testing and assessment specialists met in Syracuse, New York, to consider a major revision of Bloom’s Taxonomy. Deciding that a revision was both necessary and feasible, they worked over the next 5 years to prepare a volume that was published in 2001.

The Revised Bloom’s Taxonomy (RBT) contains two dimensions. The *cognitive process dimension* represents the verbs included in objectives. The cognitive process categories were derived from the six categories of Bloom’s Taxonomy: *remember* (replacing *knowledge*), *understand* (replacing *comprehension*), *apply*, *analyze*, *evaluate* (moved one position lower on the continuum), and *create* (replacing *synthesis* and moved one position higher). The *knowledge dimension* represents the objects of objectives. This dimension includes four generic types of knowledge that transcend specific subject matters: (1) factual knowledge, (2) conceptual knowledge, (3) procedural knowledge, and (4) metacognitive knowledge. Within the framework of the RBT, the objective mentioned earlier, “The student will learn to classify poems,” is of the form “The student will understand (which includes classify as a specific process) conceptual knowledge (because we’re interested in *types* of poetry rather *specific* poems).”

Using the RBT to examine objectives provides curriculum developers with a more complete understanding of specific objectives. Too often, the focus is on the content only. Teachers teach novels, fractions, mammals, conquests, Impressionism, jazz, and lacrosse. Increasingly, however, curriculum developers and educators have come to understand

that learning involves more than simply encountering—perhaps memorizing—content. Learning involves interacting with and acting on the content in various ways. These “ways of acting” are represented in the RBT by the verbs included on the cognitive process dimension. Students can learn to *remember* the authors of specific novels. They also may learn to *interpret* the actions of characters within the novels or *explain* the impact of the setting on the tone of a novel. Eventually, they may learn to *evaluate* the quality of specific novels and, perhaps, *create* a novel of their own. These are only five of the myriad of objectives that can be built around the study of the novel. They differ not in the content, but in the cognitive processes required of the student.

With this increased understanding of intended learning outcomes, curriculum developers can move to the question, “How can we design instruction so students learn what we expect them to learn?” Importantly, similar instructional strategies are needed with objectives of common RBT forms. Learning to classify, for example, is facilitated by instruction that enables students to understand the key differences among the categories under consideration (e.g., fiction vs. nonfiction, rational vs. irrational numbers). It also requires instruction that allows students to classify for themselves, rather than watch the teacher classify.

Examining objectives through the lens of the RBT also enables curriculum developers to design valid and reliable assessments of student learning with respect to the objectives. Assessing students’ ability to classify requires that students are asked to place a set of specific instances into various categories. They also may be asked to give a rationale for their placement so that curriculum developers know that they understand the basis for their classifications.

Ultimately, by using taxonomies such as the RBT, curriculum developers are able to increase the alignment among three critical components of curriculum: objectives, instruction, and assessment. Curriculum alignment, in turn, increases the validity of assessment and the effectiveness of instruction. Taxonomies, then, help us understand what is worth learning and help us design educational systems that are likely to help large numbers of students successfully achieve goals and expectations.

## TAXONOMY OF EDUCATIONAL OBJECTIVES, HANDBOOK I: COGNITIVE DOMAIN

---

Robert Hutchins's General Education Plan for the undergraduate division of the University of Chicago, which he introduced shortly after assuming the presidency of the university in 1931, included an innovative curriculum. The curriculum consisted of 14 yearlong comprehensive courses, each integrating an academic discipline—the physical, biological, and social sciences, and the humanities. Students demonstrated mastery of each course within the curriculum by passing a comprehensive examination that could be administered at any time. By stating the requirements for graduation in terms of examinations to be successfully completed, it was believed that students could be helped to see that they had responsibility for decisions about the rate at which they would complete the college program, as well as decisions about class attendance and the proper amount and method of study.

The responsibility for developing basic principles for constructing examinations that were aligned with course objectives as well as administering and scoring the examinations fell to a board of examiners, the head of which was known as the university examiner. In 1943, Benjamin S. Bloom assumed the role of university examiner at the

University of Chicago, replacing Ralph W. Tyler, his mentor. Five years later, Bloom organized an informal meeting of university examiners at the American Psychological Association convention. After considerable discussion, there was agreement that the development of a common framework that could be used to classify curricular goals and course objectives would be useful in promoting the exchange of test items aligned with various types of objectives. At Bloom's urging, this framework would be known as a taxonomy and was published under the title *Taxonomy of Educational Objectives, Handbook I: Cognitive Domain*.

Because of its focus and purpose, David Krathwohl has noted that the taxonomy was originally known as the "examiners' taxonomy." After reviewing the differences between the pre-publication copy of the taxonomy with the final copy, Lauren Sosniak pointed out that although the opening paragraph of the final copy indicates a desire to be of help to persons engaged in curriculum studies and design, there is ample evidence that the volume was *not* intended to serve curriculum work. As time passed, however, an increasing number of curriculum specialists, particularly those associated with state departments of education in the United States and those associated with ministries of education in countries outside the United States began to use Bloom's Taxonomy in their work.

Based on objectives provided by faculty teaching a variety of college and university courses, the designers of the taxonomy were able to identify six major types of objectives that cut across all academic disciplines. They labeled these types, or categories, knowledge, comprehension, application, analysis, synthesis, and evaluation. As designed, the categories formed a cumulative hierarchy. That is, the categories were arranged from simple to complex, with each more complex category building on and incorporating each lower category.

Criticisms of the taxonomy began to appear almost immediately after its publication. Three of the most frequent criticisms were the following:

1. The categories are overly behavioristic, with an emphasis on student behavior rather than on student learning. Consequently, there is the risk of confusing an objective (desired learning) with its indicator (student behavior).

2. The validity of the assumption of a cumulative hierarchy is questionable. Certain demands for knowledge are more complex than certain demands for analysis or evaluation. Thus, the lockstep sequence underlying the taxonomy is simplistic and naïve.
3. Not all important learning outcomes can be made explicit or operational. Furthermore, the ease of stating objectives differs greatly across the curriculum, from one subject matter to another.

Despite these criticisms (and more), the taxonomy has stood the test of time. It has been translated into at least 21 languages. A search of Internet sites indicates that it is still being used to guide curriculum specialists, test developers, and teachers in the practice of their crafts. In a field marked by wide pendulum swings, why has Bloom's Taxonomy not only survived, but prospered? Three primary reasons can be given.

First, by examining objectives through the lens of the taxonomy, educators became aware (and remain aware) of the degree of emphasis in the curriculum that is placed on objectives falling into the lowest category, knowledge. As a consequence, many curriculum specialists began to call for an increase in so-called higher-order objectives.

Second, with its emphasis on intended learning outcomes, the taxonomy shifted educators' attention away from instructional activities to a concern for what students were expected to learn from these activities. This distinction between what teachers say and do and what students actually learn as a result of what they say and do remains a topic of much discussion and debate among curriculum specialists and classroom researchers.

Third, the taxonomy has been particularly useful in helping novice teachers focus their work, set their priorities, and appreciate their considerable role in defining the curriculum for students in their classes. These teachers reportedly have found the taxonomy quite useful in planning for a desired balance or range of cognitive demands on students as well as the learning opportunities that should be provided to help students meet those demands.

Although both criticisms and contributions of the taxonomy abound, the taxonomy has played a

significant role in the development of ideas about schooling.

## TEACHER AS RESEARCHER

---

When teachers become researchers, they take on an expanded professional role that involves systematic, self-reflective, intentional inquiry into aspects of classroom practice. In addition to regular teaching duties, they engage in question posing based on perceived educational problems, collect and interpret data, and write up their findings in the interest of improving practice. This new role for teachers is consistent with a number of values and trends in the field of curriculum studies. First, teacher inquiry is primarily concerned with understanding educational experience. When teachers develop a deeper understanding of an educational situation, their capacities for wise judgment and sound decision making are improved, thus improving the quality of the educational experience for students. Second, when teachers conduct research into their practice, it disturbs the historic hierarchy in which research into curriculum and teaching is conducted by university-based social science researchers or discipline-based academics, and teachers are positioned as consumers of research findings who apply this new knowledge. At the heart of the teacher-research movement is an assumption that teachers can and should be

generating knowledge and theories about teaching that are grounded in actual practice, as opposed to merely implementing the findings of expert, outside researchers. Third, many feminist curriculum scholars have concerned themselves with the theory-practice divide in educational work, and acknowledging the teacher as researcher further blurs the boundaries that separate these domains. Finally, the recognition of the teacher as researcher acknowledges the field's critical commitment to the democratization of the educational workplace, including classrooms, schools, and the arena of policy. In optimum settings, conducting research gives teachers enhanced responsibility, autonomy, and control over their labor, and teachers who feel thus empowered in their work are more likely to be sensitive to the democratic dimensions of their students' experience in the classroom.

This entry begins with a brief background of teacher research and then explains how it differs from conventional research. Next, this entry describes common teacher research approaches, data collection and analysis, and the purposes of teacher research. Lastly, this entry discusses criticism associated with teacher research.

### Background

Teacher research emerged in the United Kingdom, the United States, and Australia in the early 1970s and assumed a prominent role in mainstream discourses about teaching in the 1980s. Following the publication of *A Nation at Risk* in 1983, there were a variety of government efforts to improve teaching, including setting higher state standards for teacher certification and licensure and increased emphasis on teacher testing. At the same time, a number of highly visible professional organizations including the Holmes Group, the National Board for Professional Teaching Standards, and the Carnegie Forum focused attention on improving the preparation of teachers and professionalizing the teaching force through promoting teacher leadership and new school structures such as professional development schools. Concurrent with these large initiatives, grassroots teacher-led projects such as the National Writing Project, Philadelphia Schools Collaborative, the Prospect Center, and the North Dakota Study Group focused on developing the inquiry capacities of

practitioners committed to the improvement of curriculum and teaching as well as collaborative school structures to support inquiry-based teacher learning. Efforts to professionalize teaching and the emergence of teacher-led inquiry projects emphasized a new view of the teacher as a knower, a thinker, and a generator of knowledge. Teacher as researcher is a role that has developed alongside this shifting view of the teacher and suggests a deepened concern for the cultivation of intellectual capacities and analytical proficiency as well as practical pedagogical skills. Today, teacher research is a thriving movement that has attained significant validation from the broader education research community, with special interest groups devoted to it in professional organizations including the National Council of Teachers of English (NCTE) and the American Educational Research Association (AERA), grant funding and support available through professional bodies such as the U.S. Department of Education's Office of Educational Research and Improvement (OERI), and increased venues for the publications of studies carried out by teachers.

### How Teacher Research Differs From Conventional Educational Research

Many teacher-research texts highlight the differences between conventional educational research and teacher research. Some of the contrasts they draw include who carries out the research (university-based researchers vs. classroom-based K–12 practitioners); the purposes of the knowledge generated (findings that can be generalized to other settings vs. applied in the setting in which they were discovered); where research questions originate (analyses of theoretical or empirical studies vs. “felt difficulties” in specific contexts); issues of data and analysis (peer reviewed research standards vs. alternative forms of discourse and analysis); theoretical frames (derived from the social sciences and the humanities vs. derived from knowledge of professional practice and disciplines specific to education); and other ethical, methodological, and epistemological issues such as the cognitive stance of the researcher (objective vs. subjective). These contrasting visions of what counts as research are often invoked to discount teacher research. Conversely, there is a growing recognition in the professional research

community of the importance of understanding more about context and the particularities of educational situations in the quest to better understand complex educational problems. Most teacher research is not required to go through institutional review board approval processes because it is inquiry carried out in the normal course of teaching, is not experimental in nature, does not require a control group, and is not subject to the same methodological standards around issues such as sample size, verifiability, or the generalizability of findings.

## Approaches

### *Action Research*

Most research carried out by teachers comes under the umbrella of action research. Action research is a cyclical inquiry process that involves problem-posing, fact-finding, planning, acting, reflecting, and evaluating the results of the actions. Action research has a spiral quality; based on the evaluation of results, one then enters into the cycle again, with further analysis, fact-finding, planning, and so on. This approach to research is associated with the solving of social problems (early topics were social violence and racial discrimination), and action research theorists emphasize the importance of including practitioners, not just expert researchers, in all phases of inquiry. Theorists have identified three main forms of action research that represent contrasting methods, purposes, and values.

*Technical* (sometimes referred to as *positivist*) action research characterized early forms of action research. It often involves differential power relations between “experts” and “practitioners” and is oriented toward greater efficiency and effectiveness in practice.

*Practical* (sometimes referred to as *deliberative* or *interpretive*) action research is more egalitarian than technical research and involves interactive communication, collaboration, deliberation, negotiation, detailed description, and interpretation. It is oriented toward understanding practice and solving practical problems, with an emphasis on improving the judgments that practitioners make.

*Critical* (sometimes referred to as *emancipatory*) action research is more explicitly tied to

issues of social justice and participatory democratic processes than are technical and practical action research. Critical action research is also more reliant on theory as a guide to emancipatory action, rather than on relying solely on practical wisdom or empirical observations.

Because of its usefulness in solving real-life problems, its potential for collaboration and collective inquiry, and its fundamentally democratic character, action research is particularly well suited to teacher research. Educational action research currently finds wide expression in international, national, and regional networks and collaboratives, professional organizations, a number of online journals, archives of studies, and many texts devoted to the subject.

### *Descriptive Inquiry*

Developed out of the work of the Prospect School and later the Prospect Center, under the leadership of Patricia Carini, *descriptive inquiry* is a form of practitioner research derived from phenomenology that focuses on close observation and the detailed written description of perceptions. There are three types of descriptive inquiry work: (1) the descriptive review of a child, (2) the descriptive review of practice, and (3) the descriptive review of student work. Studies culminate in shared oral inquiry processes that are oriented toward developing deeper pedagogical understanding and informed practice. Advocates of this form of teacher research believe that disciplined perception works to overcome habitual perception and conditioned biases, broadens the range of pedagogical actions and responses, and allows for deeper layers of meaning to emerge from classroom events. By being more attentive to their present circumstances, it is assumed that teachers will be better equipped to transform their practice in ways that support the fuller humanity of their students, transform their classrooms toward greater equity and social justice, and foster student understanding of curriculum content. Descriptive inquiry groups operate in many schools nationwide.

Descriptive inquiry and action research are related activities that differ in intent and method. Both methods pose questions based on “felt difficulties” in practice. Although action research is focused explicitly on pragmatic problem solving,

descriptive inquiry is more concerned with developing deep understanding and overcoming habitual ways of thinking. In action research, reflection is valued, but it lacks the grounding in philosophical phenomenology that might support a deeper awareness of one's biases and assumptions and their roots in the social construction of consciousness. Action research is more likely to be "scaled up," whereas descriptive inquiry tends to stay closer to the site of its origin. Both methods lend themselves to collaboration at every level: the levels of problem posing, study design, data collection, and interpretation, and in the evaluation and sharing of results. Both approaches share with each other, and with the larger qualitative research community, methods of data collection and interpretation specific to the educational enterprise.

### Data Collection and Analysis

Teachers have a substantial variety of data gathering methods and tools available to them. Much of the data consists of artifacts generated in the everyday work of teaching: student work samples, anecdotal records, grade reports, running records, and attendance records. Additionally, teacher researchers use field notes or detailed written observations, surveys, interviews, peer observations, and reflective journals to record events and conversations specific to their research question. Many teachers make use of audiotape, video, classroom maps, or photographs to provide additional evidence for consideration.

Teacher-research texts provide advice on various methods of coding, sorting, organizing, and analyzing the collected data that is similar to that found in the qualitative research literature. Just as qualitative researchers write up the results of their findings, teacher researchers also construct narratives using the data they collect to tell the story of what they have learned and provide evidence to back up their conclusions. Sometimes their studies conclude with policy recommendations, or with suggestions for further study.

### Purposes

#### *Improved Practice*

The primary function of teacher research is to improve practice at the classroom level. Teachers

who engage in systematic inquiry attend more carefully to their teaching methods, their interactions with students, their understandings about the complexities of student learning, the unintended consequences of their actions, and the various ways that students experience the curriculum.

#### *Preservice Preparation*

Many teacher education programs include some form of teacher research in their preservice preparation programs. Often, the inquiries are carried out during the student teaching semester or year, and students attend a concurrent seminar at which they discuss their ongoing findings. Including teacher research in teacher preparation programs is thought to enhance new teachers' capacities for objectivity, informed decision making, understanding diversity, meeting students' learning needs, taking a more active role in school change and policy, and curriculum development.

#### *Professional Development*

Many postcertification graduate courses and programs include building capacity for inquiry. Often, teachers carry out a long-term project toward completion of their master's degree. Teacher research is increasingly seen as an essential part of the professional career ladder, leading to teacher leadership roles, mentoring new teachers, participation in school–university partnerships, school-based decision making, peer support, coaching, staff development, policy work, or national board certification, for which teachers are required to provide evidence, and to analyze and reflect on aspects of their teaching.

#### *School Change, Reform, and Renewal*

Teacher research is sometimes part of school or districtwide initiatives to improve curriculum or teaching practice. When a sufficient number of teachers in a school are teacher researchers, a "culture of inquiry" can be established that promotes the development of collaborative dispositions, engagement in collective problem solving, and the establishment of more respectful and supportive work environments. With the current emphasis on data-driven instruction, teacher research helps

educators to be more deliberate in documenting and evaluating their efforts toward improved student learning, and although teacher research is anecdotally related to improved student outcomes, there is insufficient evidence to make broad claims about this.

### Policy

Teachers who carry out systematic examination and assessments of their practice are better equipped to contribute to policy discussions. There is a growing recognition that policy will be more successfully implemented if practitioners are a part of the process by which policy is deliberated and created. The Teachers Network Policy Institute (TNPI) is one national organization dedicated to teacher research whose members take an active role in trying to influence policy so that it might be more responsive to the realities of classroom life.

### Critiques

There is criticism of teacher research from the research community and from practitioners themselves. Researchers charge that teacher research lacks methodological rigor, lacks control over independent variables, is weak in internal and external validity, lacks objectivity, is not subject to recognized forms of logical interpretation, is not generalizable to other settings, and is difficult to replicate because of inadequate information about how the research was conducted. These charges can be answered with reminders about the context-specific nature of teacher research, its primary intent to improve practice, and its qualitative contribution to the body of knowledge about the craft of teaching.

Internal criticisms of teacher research have more to do with problems of implementation: having adequate time to carry out the research, the challenges of teaching while researching, having supportive school structures in place, having the necessary knowledge and skills to carry out and communicate the research effectively, having control over the nature and content of the inquiry, and feeling that the knowledge gained is valued and has purpose. The “teacher as researcher” must overcome well-entrenched, internalized ideas—often supported by policy, practice, and

regulation—about what counts as legitimate knowledge, who should make decisions about appropriate instruction, who determines what students should know, who designs curriculum, and the limits of professionalism.

## TEACHER AS STRANGER

---

*Teacher as Stranger: Educational Philosophy for the Modern Age* was published in 1973, and it remains one of the most inspiring and powerful of

Maxine Greene's numerous writings. Greene, one of the preeminent philosophers in the worldwide field of education, directs this book to those who teach in classrooms settings. She challenges all teachers to "do philosophy"—to think philosophically about what they are doing—so they will become "self-conscious" about political, personal, social, and cultural influences on constructions of teacher roles and identities as well as of conceptions and enactments of curriculum.

Greene argues that all teachers as well as educational philosophers should be posing moral and political questions in relation to the purposes of education. *Teacher as Stranger* invites all educators to consider what Greene sees as necessary considerations of what constitutes freedom, choice, and acts of responsibility within classrooms that are situated in often unjust and inhumane larger worlds.

Greene writes as an educational philosopher who identifies herself as an existential phenomenologist. She explicates assumptions and perspectives of such a positioning by articulating the daily need to awaken from habitual ways of being and doing in the world, to hold oneself accountable for one's choices, to be an informed and active participant in the public world. Greene investigates a variety of historical influences and philosophical orientations that could be applicable for teachers who wish to act on their commitments and, at the same time, to set others free to be. Greene wishes, through her numerous analyses of cultural phenomena, especially in the arts, to arouse teachers to wide-awakeness. Through such analyses and, in particular, through her positing of the arts as offering possibilities for self-confrontation and self-identification, she urges teachers to become critically conscious of the need to break out of a one-dimensional view of themselves as well as their limited realities to attend to all that is involved in the complex processes of teaching and learning.

Thus, Greene weaves her metaphor of "teacher as stranger" through myriad examples of pedagogical and curricular decisions that teachers must consider. Greene provides sophisticated assessment of historical influences on and philosophical considerations of the nature of man (Greene later has written about her embarrassment at her exclusive use of "man" and "he" in her early writings), of his being and learning, of various approaches to

beliefs and truths, and of attempts to choose "the right." By so doing, Greene provides teachers with understandings that might enable them to take a stranger's vantage point on everyday life to look inquiringly and wonderingly on the world in which they and their students live.

Greene situates her argument for "doing philosophy" within a contemporary framework by employing then-current examples from literature, media, the arts and political movements, including the protests against the war in Vietnam as well as the civil rights and women's rights movements, for example. Greene does so to support her contention that teachers must consider a pluralist U.S. society and recognize the necessity, in both classroom situations and curriculum constructions, of honoring multiple ways of seeing the world.

Greene suggests that teachers first must attend to their unique biographical standpoints before they can constitute their own meanings of teaching and curriculum, for example, within the contexts of their particular cultures and environments. Recognizing patterns in the ways teachers construct their own realities becomes an important thematic consideration throughout *Teacher as Stranger*. Greene is concerned that teachers become more self-conscious about the multiple schemata needed to interpret modern life to become more responsible in the choices they make among available ways of seeing and interpreting the world.

Greene especially highlights dimensions of various epistemological assumptions that undergird various philosophical perspectives. She discusses influences and emphases of philosophic rationalism, empiricism and pragmatism, phenomenology, and existentialism so that teachers might then clarify their own epistemological positions and to be aware of consequences and influences of those positions on students studying in their classrooms. At the same time, Greene acknowledges that students are active and always changing, and therefore teachers must choose intentionally and with wide-awakeness those particular curricula or pedagogical strategies that address particular students' needs.

Greene's constant concern with curriculum is that it not be external to the search for meaning. In this beautifully written and still vital book, Greene argues that if teachers can situate themselves as *strangers*, they can make themselves

visible to themselves to counteract meaninglessness and isolation of individuals who every day must choose—choose to learn, to teach, to take action in the world.

## TEACHER-CENTERED CURRICULUM

---

*Teacher-centered curriculum* refers to a body of assumptions about the purposes of education, beliefs about knowledge, learners, and learning observable in teacher behaviors and classroom practices. Teacher-centered curriculum embraces an orientation toward education as a venue for socializing students toward enacting their roles in society through mastery of particular skills and traditional values. Beliefs associated with teacher-centered curriculum focus on specific knowledge, including official curriculum and core curriculum. From this orientation, knowledge becomes a commodity transmitted from teachers to learners who are presumed to be receptive vessels. Teacher-centered curriculum is most effectively and efficiently transmitted through methods that impose curricular order and is characterized by pedagogical methods that presume teacher as authority, learning through repetition, and learning as a quantifiable outcome. Teacher-centered curriculum is usually presented in contrast with the concept of child-centered or student-centered curriculum.

Teacher-centered curriculum does not have a history of its own separate from its contrastive connection with student-centered curriculum. Accounts of teacher-centered curriculum most often appear in the research literature as a contrast

for descriptions of student-centered, constructivist, or project or problem-based approaches to curriculum. From as early as the 1800s, this has been the way curricular theorists have labeled curricular practices where the teacher is in the active role with students in passive roles. Teacher-centered curriculum has such an intractable quality in that despite prolonged efforts to displace it with student-centered curriculum, it continues to be an accurate description of the curricular practices of most teachers regardless of grade level. Because of the resilience of this approach, one wonders whether curricular theorists might not examine more carefully why such a curricular approach endures.

As early as 1920, educational research explored the question of whether teacher-centered or student-centered curriculum produced greater learning in its students. This question did not emerge because there was a tradition of excellence in teacher-centered curriculum, but because researchers were trying to promote a discussion approach to curriculum to combat lecture methods that were already in place. These researchers labeled any kind of instruction employing lectures as teacher-centered, whereas the new improved discussion approach they were promoting was labeled student-centered. In the literature and research on curriculum practices in the schools, this continues to be the case. Educational researchers develop new techniques and practices that involve more student input and interaction, which is contrasted with more traditional practices. The approaches using more student input and interaction are labeled student-centered, and all other traditional practices are identified as teacher-centered. Currently, teacher-centered curriculum is represented in essential schools, direct instruction, or educational practices that emerge from belief systems, which promote schools as sorting mechanisms. Teacher-centered curriculum often emerges as the culprit in arguments about social reproduction, hegemonic practices, and social inequality.

When teacher-centered and student-centered curricula are contrasted, the differences between the two are often characterized by instructional practices or pedagogy rather than in curricular terms. Yet, when one considers them from a curricular rather than a pedagogic approach, it becomes more difficult to distinguish between them. A teacher might have a teacher-centered

curriculum yet practice student-centered pedagogy. Conversely, a teacher who embraces a student-centered curriculum may enact teacher-centered pedagogy. For example, based on research, which indicates that poor and minority students perform better in highly structured and orchestrated classroom environments, some school districts may mandate forms of teacher-centered pedagogic practices. Yet, teachers within such schools might embrace students as co-learners, enact their authority more as a responsibility than control, take inquiry approaches to content, and create a culture of democratic practices in their classroom. Although the teacher-centered pedagogy might be more immediately observable, the curricular practices of the teacher are actually more aligned with student-centered curriculum. Teachers' pedagogic practices typically reflect their curricular orientation. Therefore, teacher-centered curriculum usually involves a classroom culture in which the teacher is the singular authority, students are passive, and curricular content is nonnegotiable and is visible in both the curriculum and pedagogy.

watered-down college academic curriculum resulting in insufficiently responsive schools to the educational needs of gifted and talented students. It was widely believed that U.S. children lagged behind their Soviet counterparts. Events of the 1960s lead to more criticism, but the charge was irrelevancy, particularly that the school curriculum was unresponsive to the needs of urban and minority children. Since that time, wave after wave of educational reform has followed, and with time, state and federal governments have become the dominant forces in curriculum reform within both public education and teacher education. This trend accelerated following publication in 1983 of *A Nation at Risk: The Imperative for Educational Reform*. Presently, teacher educators have relatively little control over the curriculum of teacher education. This entry discusses several aspects of teacher education curriculum, including reforms, the professionalization of teaching, the involvement of the faculty, and the contradictory movements toward greater standardization and greater variability.

#### Teacher Education Curriculum Reform

Reforms of the late 1960s and early 1970s in teacher education proceeded along two very different lines, representing contrasting conceptions of teaching and learning. Generally, additional credit hours were not available, so changes took place within established institutional boundaries. Seeking to change school teaching practices, one group of teacher educators embraced humanistic psychology, which found a place alongside established behaviorist practices. Inquiry and various approaches to group work and human relations gained prominent places in methods courses. In time, open or informal education practices imported from England swept into early childhood and elementary teacher education. Experimentation with different patterns of student teaching, including team teaching, took place. Echoing the values of forgotten progressive education practices, student needs and interests were given an elevated place in curriculum decision making where intrinsic was preferred to extrinsic student motivation and active learning emphasized. Beginning teachers increasingly were urged to become agents of social change. The spirit of the 1960s and 1970s is

## TEACHER EDUCATION CURRICULUM, PRESERVICE

---

Criticism of the established curriculum of undergraduate preparation of teachers began in the 1950s. Critics accused teacher educators of supporting a

evident in the titles of Association for Supervision Curriculum Development yearbooks: *Perceiving, Behaving, Becoming: A New Focus For Education; Education for an Open Society; Schools in Search of Meaning; Feeling, Valuing, and the Art of Growing: Insights Into the Affective.*

Paralleling these developments, a second group of teacher educators drew inspiration from the findings of process-product research, and embraced instructional technology and various models of individualized instruction, partially in response to charges reminiscent of the 1950s, that students were not performing academically as well as they could or should, but also to charges of irrelevancy. Competency-based teacher education emphasizing mastery of specific skills associated with effective teaching grew in influence, and greater emphasis was placed on the assessment of learning. Researchers identified skills associated with effective teaching, classroom discipline, and group management. Jacob Kounin's list included withitness, overlapping, smoothness, momentum, group focus, and positive group alerting cues. Earlier, publication of the *Taxonomy of Educational Objectives: Cognitive Domain*, edited by Benjamin Bloom and published in 1956, and the *Taxonomy of Educational Objectives: Affective Domain*, edited by David Krathwohl and published in 1964, transformed the curriculum of teacher education, becoming part of the teaching of unit and lesson planning across the nation for both groups. The taxonomies provided a means for thinking systematically about educational aims and, when formed as behavioral objectives—statements of what students are to be able to do and under what conditions they are to do it as proof of learning—provided means for assessing learning outcomes and individualizing instruction. For a time, microteaching, which involved teaching discrete instructional skills to peers, videotaping the performance, and then receiving criticism on that performance, enjoyed a prominent place in methods courses.

### Professionalization of Teaching

Increasing global competition and the economic ascent of Japan raised concerns about U.S. competitiveness and with growing concern yet another round of intense educational criticism began. *A Nation at Risk* galvanized public opinion around

the belief that U.S. schools were failing and primarily were responsible for worsening economic conditions. In response, academic standards for students and their teachers were raised, the school curriculum trimmed and standardized, and technology, science, and mathematics elevated in importance. The aim was excellence in education, and proof of excellence came in the form of rising standardized test scores. Few asked whether schools could possibly be responsible for the then-current economic conditions.

Hundreds of reports followed *A Nation at Risk*, many urging a reduction in the amount of time spent by future teachers in professional studies, excepting student teaching, and strengthening academic majors for teachers. Prompted by the Carnegie Forum on Education and the Economy that proposed formation of a national board for professional teaching standards and, foreshadowing future events, linking incentives for teachers to schoolwide student performance, and by the Holmes Group, a consortium of deans of education in research universities, teacher educators turned to the professionalization of teaching in response to critics. The claim of teacher educators was that teaching, like other professional practices, involved special knowledge and ability. To make the case for the value of professional studies required that the subject matter of teaching and learning be codified and taught. The American Association of Colleges for Teacher Education sponsored volume, *Knowledge Base for the Beginning Teacher*, was among the more prominent efforts to identify the knowledge base of teaching. Pedagogical content knowledge became an important concept for rethinking methods course content. Interest grew in teacher expertise and learning and the curriculum of teacher education became somewhat more sensitive to the developmental issues of beginning teachers.

Embracing professionalism, the Holmes Group argued that the work of teaching should be staged and supported career ladders with different levels of responsibility and reward for teachers. Additionally, it was thought that all teachers should have academic majors and minors, and that the elementary education major should be abolished. To provide sufficient time for deeper academic study, the Holmes Group championed postbaccalaureate teacher education. Eventually

several members of the group dropped their 4-year programs and developed 5th-year and graduate certification programs only later to reconsider the decision as enrollments declined. Additionally, the group argued for the value of student cohorts—groups of beginning teachers who proceed through their courses together—as essential to forming a professional ethic and identity. Cohorts proved powerful means for overcoming program fragmentation but, perhaps more importantly, were found useful for developing the ability and disposition among beginning teachers to invest in one another's growth. Reconsidering the relationship between universities and schools was an essential element to the Holmes agenda. The argument was that like medicine, teacher education required labs, and schools were the laboratories for teacher education. Partnerships or professional development schools (PDSs) formed a critical element in the agenda and a wide variety of partnerships were formed across the nation. Of these, perhaps the most influential have been those associated with the National Network for Education Renewal (NNER) formed by John Goodlad and his associates in the Institute for Educational Inquiry. Supporting Goodlad's vision, the NNER remains committed to the simultaneous renewal of teacher education and schooling, and to involving on equal footing the stakeholders of teacher education. The point is simple but powerful: Excellent teacher education requires excellent schools.

### Faculty Involvement

In many, not all, teacher education institutions, greater involvement of teacher education faculty within schools positively influenced the curriculum, enabling design of programs of study more responsive to classroom life and school practice. In many partnerships, as the work of teacher education became more widely shared, the long-recognized gap separating theory and practice narrowed. Also, increasing involvement of university faculty in schools resulted in new patterns of staffing, particularly the growth of clinical faculty of various kinds and new forms of research and relationship. By the late 1980s, and continuing, mentoring became an important component of successful teacher education programs.

### Greater Standardization Versus Greater Variability

*A Nation at Risk* and its aftermath encouraged a dramatic increase in legislative involvement in education, including teacher education, that has continued unabated. The pathway leading from *A Nation at Risk* to No Child Left Behind (NCLB) is straight and narrow. Ironically, two conflicting patterns of teacher education reform followed, one encouraging greater standardization and the other greater variation. Standardization was linked to both the quest for professionalization as well as to legislative interest in greater accountability. In 1987, the Interstate New Teacher Assessment and Support Consortium (INTASC), a program of the Council of Chief State School Officers, was formed to encourage collaboration across states to gain greater uniformity in initial licensing, preparation, and induction. Ten standards were identified along with performance indicators. As described in a 1992 publication, *Model Standards for Beginning Teacher Licensing, Assessment and Development: A Resource for State Dialogue*, the ten standards quickly found their way into state accrediting systems and into teacher education. Effort followed to create a single set of standards, which was accomplished in 1996 with the alignment of the 10 INTASC standards with the 6 standards used by the National Council for the Accreditation of Teacher Education (NCATE) for accrediting teacher education institutions and the National Board Teaching Standards for inservice teachers.

Formed in 1954, NCATE has become a major force for raising standards, creating greater program uniformity, and for making the argument that teaching is a profession. Until the late 1990s, program accreditation was based on the presence of a set of institutional conditions—opportunities to learn—thought related to becoming an effective teacher. By the late 1990s, facing growing accountability pressures, program emphasis shifted to outputs. To be accredited, teacher education institutions are now required to develop evaluation systems that provide compelling evidence of the quality of graduates' teaching performance, content area and pedagogical knowledge, teaching skill, including evidence of impact on pupil learning, and possession of valued attitudes and dispositions toward teaching and learning, especially

toward diverse student populations. With strong legislative support, meeting INTASC and NCATE standards has become the driving force behind teacher education curriculum development.

New forms of teacher education candidate assessment have been developed, most especially portfolios and teacher work samples that often become a unifying thread across courses. Since the 1960s, greater attention has been given to diverse learners, and concomitantly to providing more varied field experiences. Gradually, ethnic studies, multicultural, and bilingual education courses replaced established foundations courses. When required, technology courses shifted to emphasize the instructional uses of computers and away from more traditional forms of media. Since the 1980s, special content area methods courses have replaced general methods courses. As part of encouraging professionalism, where the distinctive feature of a professional is that one learns from one's experience, action research has found place in some institutions.

With greater appreciation of the diversity in pupils' cultural backgrounds and experience, a result of dramatically shifting national demographics, there also has arisen greater appreciation of the need for a more diverse teaching force. Supported by constructivism, a view of learning that recognizes the contribution of the learner to what is learned, interest during the past 20 years also has grown among teacher educators in teacher beliefs and attitudes and in how the stories of their lives and the nature of their experience shape the kind of teachers they become. Within some teacher education institutions, these interests have a place within the curriculum. Recognizing that school subjects come to students through the experience and understanding of teachers, life history studies and autobiography are sometimes integrated into existing courses.

The second pattern of reform, that promoting greater variation, enjoys considerable support within several state legislatures. A common perception has been that rather than enhance teacher quality, teacher education programs make it difficult for able people to become teachers. In time, alternative forms of certification were approved in every state, and in some states—Texas and New Jersey, for example—maximum hours allowed for teacher education were dramatically cut. Sometimes

sponsored solely by school districts facing teacher shortages, a common pattern was and is for a person possessing a college degree to teach as a provisional teacher for a year while receiving various kinds of support. Certification follows successful completion of the year.

Despite a great deal of activity and innumerable attempts to convince policy makers that teaching is a profession and that teacher educators could be trusted to make wise curricular decisions, ultimately the effort failed. Passage in 2001 of the NCLB legislation coupled with ever-increasing legislative activism in education within the states and recent changes in accreditation systems to tighten standards, teacher educators have lost nearly all control over their programs, except at the margins. This is the case even though, under NCLB, states and school districts were promised greater flexibility in the use of federal funding. Currently, there is remarkably little discussion of school or teacher education program aims. In effect, standardized tests used to determine adequate yearly progress of individual students and make judgments of school quality set the aim of education, an aim that teacher educators necessarily embrace. Given a paucity of courses and of time, the teacher education curriculum has come to be tightly linked to specific externally set standards and standard indicators, an essential condition for passing a NCATE accreditation review.

There is, however, a small but growing counter-movement. Founded in 1997, and gaining approval as a teacher education accrediting body by the U.S. Department of Education in late 2003, the Teacher Education Accreditation Council (TEAC) offers an alternative to NCATE. In contrast to NCATE, which embraces an external standards model for program accreditation, TEAC works from an accountancy model, seeking to establish that an institution does what it claims to do. Institutions pursuing TEAC accreditation must have clear aims and be able to provide compelling proof of meeting those aims. TEAC accreditation potentially allows greater curricular control and flexibility than NCATE offers.

### Final Thoughts

Despite their complexity and cost, public school and university partnerships continue to play an

important role in teacher education. Curriculum development when three partners—school, education, and arts and science faculty—are involved presents tremendous challenges and opportunities. In partnerships, negotiation of roles and responsibilities is necessarily ongoing. This is especially the case when, anticipating an accreditation visit, faculty opt to forge their own aims rather than adopt a set of external standards. Recognition of differences and similarities in interests and commitments of each of the partners calls for unique approaches to and models of curriculum development, those enabling cross-institutional collaboration, and offers rich research opportunities. Recently, the concept of the professional learning community has emerged as a promising approach to program improvement. When stakeholders learn together and are invested in one another's learning, program quality and impact improve. For most of the history of teacher education, curriculum reform has focused sharply on hours, courses, programs, and content, but relatively little attention has been given to those charged with development and implementation. The most promising but now only emerging trend in teacher education curriculum work is the growing recognition successful programs are most likely to be those that best support teacher and teacher educator learning over time.

## TEACHER EDUCATION CURRICULUM, PRESERVICE, HISTORY OF

---

The curriculum of preservice teacher education evolved over an extensive period and in relationship to shifting social aspirations and demographics. Always embroiled in contention and reflected in the development and evolution of a set of unique institutions, by 1950 a pattern was set that placed teacher education in a 4-year undergraduate education that included 2 years of general studies, an academic major and minor, and professional studies. Professional studies for secondary preservice teachers comprised approximately 20% of the total program, whereas these courses made up about twice that amount for elementary teachers. The relative proportions of these three components have long been a source of debate. Against this backdrop, various curriculum reform efforts have been launched. Although debate continues about the value of teacher education to quality teaching and to student learning, the curriculum of teacher education has played an important role in what is understood to be schooling in the United States.

Advocacy for the formal preparation of teachers began in Massachusetts as early as the late 18th century, but progress was uneven. Usually what was meant by formal preparation was merely the additional study of the subjects to be taught. Only later did a curriculum uniquely designed for the work of teaching emerge.

Beginning in the fall of 1839 and running for 6 weeks, the first institute for teachers was launched by Henry Barnard, the first Connecticut secretary of education. Success of the institute, which drew 26 young men, quickly led to other states

sponsoring institutes. Eventually, in addition to subject reviews the institutes offered practical teaching hints and later short courses in the theory and practice of teaching coupled with inspirational talks.

Boston industrialist and member of the Massachusetts Board of Education Edmund Dwight offered the sum of \$10,000 to establish a normal school for training teachers for the common schools of the state. Matching state funds followed and a provision was made for the establishment of three schools. Reverend Cyrus Peirce was appointed to head the first school in Lexington, which opened in July 1839. Typically, the normal school program lasted for a year and involved a thorough review of the “common branches” taught in primary schools—arithmetic, spelling, reading, writing, geography—and a few secondary subjects coupled with classroom management, methods courses, and studies of child development. Model schools were also founded, and within them student practice taught for a time. Given the shortage of teachers, very few actually completed a full year’s program. By 1900, there were roughly 250 public and private normal schools stretching from coast to coast that educated approximately one-fourth of employed elementary school teachers. At this time, most teachers had virtually no special training for the work of teaching; moreover, the common view was that none was needed.

Throughout the 1870s and 1880s, the normal school program of study expanded and lengthened to include subjects taught in high schools. However, with the rapid growth of secondary education, normal schools found themselves under attack. Of uneven quality, the perception was widely held that the normal school program of study and the quality of instruction was below that of academic secondary schools. With the expansion of secondary education and the growing need for greater numbers of teachers, colleges and universities, often reluctantly, began developing programs of study for teachers supplementary to traditional academic studies. The University of Michigan formed the first department of science and art of teaching. Other similar units followed. By 1910, and despite an uneasy relationship with established academic departments, nearly 250 colleges and universities sponsored departments or chairs of pedagogy. Heavily reliant on school practitioners,

the programs of study that emerged often were criticized for a lack of rigor and substance by arts and science faculty.

A partial solution to this problem was for a few professors in the academic disciplines to offer courses in education. In addition to the practical hints given by professors who had been school superintendents, principals, or worked within normal schools, more theoretical courses were added to the curriculum of teacher education. By the beginning of the 20th century, the curriculum generally included lecture courses in the art of teaching, instructional methods, classroom practice, and psychology, as well as courses in the history and philosophy of education.

Seeking greater uniformity and less partiality in teacher hiring and retention, states became involved in teacher licensure in the early 1900s. Establishment of state-mandated requirements for licensure led to greater program uniformity.

The first half of the 20th century witnessed a transformation of the normal school into the teachers college, the majority of which eventually became universities under pressure of growing enrollments and rising faculty ambitions. Requiring high school graduation for admission and generally emulating liberal arts colleges, the teachers colleges added liberal arts faculty, diversified the curriculum, offered degrees, and broadened purposes, and in time, teacher preparation became but one of many institutional responsibilities. Views differed regarding whether teacher education should be integrated into the 4-year program of study leading to the baccalaureate degree or be offered at the postbaccalaureate level.

By 1950, the general outlines of the curriculum of preservice teacher education were in place although criticism continued and various reforms were undertaken. Mostly the curriculum was functional and supportive of existing school practices. Most preservice teachers undertook a 4-year program of study. The first 2 years of the undergraduate curriculum was devoted primarily to general studies, usually designed to meet various distribution requirements—so many humanities, science, social science courses—and taught outside of education faculties. Most undergraduates also completed an academic major and minor in a teaching field. On most campuses, elementary education was recognized as a degree-granting major, yet

many of the courses composing an elementary major were taught outside of education schools or colleges, such classes as mathematics for elementary school teachers and children's literature. A persistent criticism of this pattern has been that elementary school teachers lacked sufficiently deep content area knowledge to adequately teach the many subjects for which they are responsible.

Typically receiving their degrees in their major area of study, secondary education academic teaching majors generally were only slightly different from other majors. Often the only difference was the addition of a methods course or two. For elementary education majors, unlike secondary education students, content and methods were blended but not necessarily integrated theoretically. Historically, there have been periods of interest in what was in the late 19th and early 20th centuries called the professionalization of subject matter, more recently characterized as pedagogical content knowledge. The idea is that to teach a subject requires knowing that subject in very special ways and especially in relationship to how it is best learned. Although championed by such notables as William Chandler Bagley early in the last century, the concept gained little traction as teacher educators deferred to the traditions of teaching in the higher status disciplines. One result was that for students pursuing secondary teaching, certification methods courses were usually program add-ons sometimes joined by general teaching methods courses that emphasized principles of unit and lesson planning, content organization, assessment, and classroom management across content areas. Additional professional courses included educational psychology, one or another foundations course—history, philosophy, sociology of education—and various practica, including student or practice teaching. Practica provided opportunities of various kinds—observation of experienced teachers, tutoring, correcting of papers, teaching of lessons, learning about how schools operated and, presumably, applying theory to practice. Lasting varying lengths of time, student teaching was and is widely thought to be the most important aspect of the professional curriculum. Working in an experienced teacher's classroom, the common practice long has been for the beginning teacher to gradually take on more and more responsibilities until assuming nearly all.

Supervision of student teaching, involving observations and provision for assessment and feedback, typically has been done by a representative of the university. Responsibility for student teacher learning fell primarily on the cooperating teacher. As such, the curriculum of student teaching was heavily influenced by the cooperating teachers' understanding of and approach to teaching, thereby presenting the possibility of conflict with the intentions of the sponsoring teacher education institution. This, then, is the pattern of teacher education as it developed, a pattern dictated by rapidly growing student enrollment and an expanding school system that struggled for much of the century simply to staff the schools and to improve the quality of education offered the young.

## TEACHER EDUCATION CURRICULUM, PROFESSIONAL DEVELOPMENT

---

Each reform initiative, each advance in knowledge of teaching and learning in U.S. education, and every plan for school improvement brings related professional development initiatives. Professional development, also known previously as inservice education and staff development, has been defined by Thomas Guskey as activities designed to

enhance the professional knowledge, skills, and attitudes of educators as a way to improve the learning of students. These initiatives have been undertaken routinely by various groups, including federal agencies, states, local school districts, schools, subject matter associations, universities, and private for-profit entities, though they have been funded often at relatively low levels, with some estimates indicating that less than one-half of 1% of school district budgets are earmarked for professional development. This decentralized, entrepreneurial array of professional development created and implemented by a wide variety of organizations, many times with competing interests, results in significant variation in formats and effectiveness of the opportunities. Although teachers in the United States have engaged in professional development activities for decades, teacher professional development opportunities and their effectiveness have been studied substantively only since the late 1970s.

For many years, teacher professional development was predicated on a deficit model rather than a development or growth or capacity building model. Staff development or inservice training was believed to provide opportunities to address deficiencies in teacher knowledge and skills related to conceptions of good practice or the implementation of innovations. The typical format for delivering these professional development activities was almost exclusively some combination of one-shot workshops, university courses required to fulfill either requirements for an advanced degree or requirements set by states or districts that teachers acquire mandated amounts of course work or continuing education units (CEUs), and guest (“expert”) speakers intended to provide motivation for teachers or to promote a school or district initiative. Such efforts often were disconnected from the work of teachers, arbitrary, and atheoretical. The typical format consisted of short, stand-alone workshops in the “sit & get” tradition without teacher input or consultation. They rarely resulted in a transfer of knowledge and skills within the classroom.

The knowledge base related to professional development for teachers began to change and mature in the 1980s. The work especially of the National Staff Development Council (NSDC) and of the Association for Supervision and Curriculum

Development (ASCD) expanded the importance, definitions, purposes, conceptualizations, and research related to professional development. A synthesis piece on models of staff development, published in 1989 by Dennis Sparks and Susan Loucks-Horsley, was especially important in bringing conceptual order and a broader and deeper theoretical basis to the field.

### Major Models

This work and others described seven major models of professional development: training, observation/assessment, involvement in a development/improvement process, study groups, inquiry/action research, individually guided activities, and mentoring.

Training, the most common form of professional development, is typified by a consultant or team of consultants who present ideas through large group presentations, workshops, demonstrations, or other active or receptive learning strategies. Training usually includes explorations of theory, presentations of research findings and inferences, demonstrations, modeling of skills, and guided or individual practice. The impact or effectiveness of training can be enhanced substantially by coaching in practice settings that follows the training. Clear objectives or intended participant outcomes based on needs assessment data or sessions codesigned by presenters and participants also can enhance transfer of training to practice. Training is the most efficient and (perhaps) cost-effective professional development model when the intent is to present a set of ideas and information with a large group of educators. The shortcoming of the training model is that it offers few opportunities for personal choice or variation and assumes the same kinds and level of knowledge is appropriate for all despite their prior knowledge or experience. Training also requires extension or additional follow-up activities for feedback or coaching necessary for successful implementation of new knowledge.

The *observation/assessment* model of professional development separates evaluation from assessment by using (usually) a collegial model in which a peer observes another peer’s teaching practice and provides information as a basis for reflection. Observation may focus on planning,

instruction, classroom management, or other issues of practice. In most models, the teacher being observed specifies the areas of practice to be recorded or assessed for future reflection. The intent of the model is that there are benefits to both observer and observed, with the observer gaining professional knowledge from watching a colleague's practice and refining the observations into usable feedback, while the peer being observed gains insight from the perspective and feedback of the observer. The disadvantage of the model is the significant commitment of time it takes for all participants to schedule and conduct conferences and observations.

Two models—involvement in a development/improvement process and study groups—are primarily group process models. *Involvement in a development/improvement* process brings educators together to design or review a curriculum or to solve a problem of instruction, organization, assessment, or learning. Done well, this model produces new learning for participants and improves their ability to work collaboratively. The negative aspects of the model are that, at times, participation is restricted to a set of task force members, and, as with other group processes, persuasive arguments can carry decisions, whether the decisions are true improvements or not. The *study groups* model involves the entire staff of a school in finding solutions to common problems. School staffs are generally divided into smaller groups (4–10), and they stay together for a school year, sometimes with rotating leadership, while they study the problem(s) and literature or experience related to the problems. Study groups and involvement in a development/improvement process are forms of learning community models and can be structured into professional learning communities as described by Richard DuFour and Shirley Hord.

The final three models are primarily oriented toward individual growth, although the first, *inquiry/action research*, can be done by a team of teacher/researchers, or even a whole school staff. This model assumes that educators have the ability to formulate valid questions about their own practice and to rigorously collect data and interpret data, using relevant and high-quality professional literature to assist in forming the problem, the questions, and the interpretations. The theory of inquiry/action research is that successful practice

will produce data-based and more rigorous possible solutions to problems of practice and will make the teacher/researchers more reflective practitioners, systematic problem solvers, and more thoughtful decision makers. The challenge of the model is that good research skills take time and practice to develop, and research studies take time, organization, and discipline to accomplish. Time in schools is not usually organized to encourage and support inquiry and action research. In the *individually guided activities* model, individual educators decide their own professional development needs and goals and design activities to achieve them. The model assumes that each individual can best decide his or her own professional development needs and that they are capable of self-direction in reading their goals. The major advantage of this model is its flexibility and capacity to accommodate needs at all stages of professional development. The challenge is for individuals to have the skill and the will to accomplish a self-decided course of action that yields productive results or produces a portfolio of learning. *Mentoring*, the seventh and final model, intentionally pairs a more experienced and knowledgeable educator with a less experienced and less knowledgeable colleague. The process provides regular and systematic opportunities for the mentoring pair to discuss goals, knowledge needs, strategies for practice, and dispositions related to the professional practice of teaching, producing student learning, and the demands of collegiality and contribution to the workplace. The process works to the degree that the mentor is credible (has appropriate experience and subject matter or grade level knowledge and skill), capable (able to work with adults, to provide constructive feedback and diagnose knowledge needs for the less experienced member), and committed (willing to schedule and structure the time needed for mentoring, willing to exert the energy and effort required for what is usually an unpaid or slightly paid professional duty).

### Standards

The NSDC Standards for Staff Development, created in 1995 and updated in 2001, helped provide a context and direction within which professional development activities could be delivered. The creation of national standards by NSDC contributed

to the 1990s as a decade of standards related to student achievement, teacher competence, professional development, and preservice teacher education. In 1992, the Council of Chief State School Officers (CCSSO) developed the Interstate New Teacher Assessment and Support Consortium (INTASC) and its affiliated set of standards (knowledge, dispositions, and performance expectations) for beginning teachers. In 1995, the National Council for Accreditation of Teacher Education (NCATE) drafted standards for the accreditation of professional education units (preparation programs), and, in the same year, the U.S. Department of Education developed its 10 principles for high-quality professional development programs and the National Board for Professional Teaching Standards (NBPTS) developed its core propositions. The National Commission on Teaching and America's Future (NCTAF), headed by North Carolina governor James Hunt and educational researcher and policy analyst Linda Darling-Hammond further underscored the movement toward standards-based teacher quality during the last decade of the 20th century.

### Professional Development in the 21st Century

Dennis Sparks and Stephanie Hirsh have suggested that a compelling set of factors including standards, constructivism, results orientation, and systems thinking are primary drivers for visions of professional development for educators going into the 21st century. Standards provide an intentional framework for developing model practices, including setting a context and working to ensure that professional development is job-embedded, opportunities are developed with student and teacher needs in mind, and teachers are involved in both the planning and implementation of professional development. Current models of professional development more often include collaboration, and they are more often evaluated for their impact on both teachers and student learning. New forms of professional development that are job-embedded or practice-based incorporate artifacts such as student work, instructional materials, lessons, and strategies that focus on student learning outcomes. Examples such as lesson study and professional learning communities incorporate these artifacts

and rely on learning from collaboration between colleagues and dialogue, rather than on outside expertise to produce new learnings in teachers and results for students. These new strategies and opportunities help embed the professional development and learning into the daily work of teachers and other educators, expand their knowledge and skills, enhance their effectiveness and competence, and lead to greater professional satisfaction. Professional development is the most readily available route to professional growth and when embedded within the daily work of teachers, with teacher input, and done in a comprehensive and systematic fashion can lead to positive outcomes including change in teacher knowledge, skill, belief, and attitudes and in increases in the attainment of specific learning outcomes in their students.

## TEACHER EDUCATION CURRICULUM, PROFESSIONAL DEVELOPMENT, HISTORY OF

---

The history of professional development for teachers has in many ways come full circle from its early days. Professional development is a set of

practices intended to change the curriculum as delivered to students in schools. Since the 1920s, teacher professional development (also known as “inservice training” or “staff development”) has exhibited elements of each of the five models proposed by Dennis Sparks: training, individually guided staff development, observation/assessment, inquiry, and involvement in a development/improvement process. Each of these models has held differently sized shares in the total “mix” of extant models in different periods.

Among the earliest eras in professional development history was the Denver Plan of the early 1920s. The Denver Plan was the work of Jesse H. Newlon, one of the country’s best-known practicing progressive administrators. Newlon, countering prevailing practice, convinced the Denver School Board that the curriculum of its schools needed to be reformed to make it more efficient, a watchword of U.S. school curriculum and curriculum theory in the 1910s and 1920s. Newlon notably was successful in convincing the Denver School Board that, because curriculum development and curriculum enactment were simultaneous and connected, classroom teachers should be the ones writing the curriculum. Further, he obtained the board’s support in paying teachers or providing release for their time outside the classroom, and he received support for providing a clerical staff to record the work of the teachers so they would not have to expend energy in these tasks. Newlon’s Denver model was in contrast to the then-frequent practice of curriculum developed by school boards in an efficiency, social control model, and it generated much interest in other school districts.

The decade of the 1930s was marked by the professional development and curriculum development activities of the Eight Year Study. The Eight Year Study (also known as the Thirty School Study) was an experimental project conducted between 1930 and 1942 by the Progressive Education Association (PEA), in which 30 high schools redesigned their curriculums and initiated innovative practices in student testing, program assessment, student guidance, curriculum design, and staff development. During the initial years of the study, the staffs at schools in the study developed their own core curricular programs. These core curricula sought to integrate and unify the separate academic subjects. A series of professional

development workshops were scheduled beginning in the mid-1930s to help teachers reconsider the basic goals and philosophy of their schools and to support the development of their own teaching materials. Follow-up studies indicated that students from the progressive schools performed as well academically and in college as did students from more traditional schools and curricula.

The late 1940s and early 1950s saw the rise of life-adjustment education, an odd amalgam of progressivism, testing and tracking, vocationalism, and therapeutic education that sought to adjust students to surrounding life circumstances. The perceived anti-intellectualism of life adjustment education, the conservatism of the McCarthy era, the close of the Progressive Education Association in 1955, the cold war, and the launch of *Sputnik* in 1957 led a return to academic curriculum reform in the 1960s exemplified by the National Science Foundation (NSF) curriculum projects (e.g., Physical Science Study Committee [PSSC] Physics, Biological Sciences Curriculum Study [BSCS] Biology, School Mathematics Study Group [MSG] Math).

A set of NSF-sponsored summer institutes provided the professional development for the NSF-sponsored curriculum projects of the 1960s. The institutes usually occurred on university campuses and were led by academics who worked with teachers to help them learn the reform-based materials that had been developed by other academics. The materials and texts were targeted toward college-bound high school students and intended as accelerants that could produce the greater numbers of scientists and mathematicians needed to overcome the perceived lead of the Soviet scientists as rapidly as possible. The materials and the institutes focused on the key concepts and inquiry modes of the disciplines they represented. However, the materials and teaching strategies from the projects and institutes proved not to be completely scalable or sustainable, and evaluation reviews of the impact and residue of the 1960s curriculum projects in the late 1970s and early 1980s found little remaining in school classrooms.

In the 1970s and 1980s, research, responses to innovation, and policy directions were drivers in professional development for teachers. At the University of Texas Research and Development Center, teacher responses to an individually guided education innovation led to the development of the

concerns-based adoption model, or CBAM. Research and evaluation studies on curriculum innovation by the Rand Corporation had earlier produced the concept of “mutual adaptation,” or the idea that innovations were adapted to the setting in practice, a counter-notion to that of “fidelity,” or faithfulness to the design of the innovation in implementation practice. The CBAM model was built on earlier research by Frances Fuller, in which she demonstrated that teachers go through stages of concerns over time. CBAM and other implementation-related theories and research studies provided a basis for observation and assessment approaches to professional development in the service of implementation of curriculum innovations during the 1970s, 1980s, and later.

The policy lever of capacity building led states such as South Carolina, as well as other schools and districts, to provide large-scale professional development (training) to improve planning and instruction and narrow variation in practice among teachers. In South Carolina, the state provided training in Madeline Hunter’s model of lesson planning across the school districts of the state so they would have a common language and procedures among teachers and in an effort to increase student achievement.

The 1983 publication of *A Nation at Risk* marked the beginning of a series of “waves of reform” in education, all of which had their counterpart manifestations in professional development. The first wave of reform—standards—began with new standards in mathematics and other content fields. Rather than prescribe practice in a “teacher-proof” endeavor to achieve fidelity, the standards movement sought to reform practice by indicating frameworks of outcomes. In professional development, the National Staff Development Council (founded in 1969) produced a set of standards for the field in 1995 that translated expected good practice in professional development for schools and districts that often gave professional development very low organizational and budgetary priority. The second wave of reform, teacher education, was marked by the publication of *Tomorrow’s Teachers* in 1986 and the advent of professional development schools. In *professional development schools*, the intent was for teacher educators to work alongside school practitioners to produce more capable and “classroom-ready”

beginning teachers, to improve the practice of the inservice teachers, to enhance the learning of students in the school, and to generate inquiry into classroom practice and student learning.

The third wave of reform was labeled “restructuring,” and involved new power-sharing and decision-making roles for teachers. In restructured schools, teachers had new roles as members of school councils or school improvement teams, and they were intended to influence decisions about curriculum, instruction, testing, and other program matters at the school level.

Although the actual practice of school councils or school improvement teams varied widely from roles confined to cosmetic improvement to genuine decentralized decisions, restructuring reforms and research on professional development in the late 20th century led to at least three types of effective current practice. The first was coaching or mentoring, in which follow-on coaching increased the effective yield of practice of an innovation or assisted teachers in improving their practice by having a peer observe, then help them reflect on their observed lesson or classroom practice. The second was large-scale district or state reform, exemplified by Michael Fullan and his colleagues, who combined strategic interventions in assessment, professional development leading to research-verified practices aimed at improving test scores, especially in basic skills and knowledge areas, and work on effective teacher decision making, especially in professional learning communities (PLCs) in efforts to improve student performance across districts or states. PLCs, in which teachers and administrators collectively engage in data-based decision making related to instructional practice and student achievement, is the most recent and current of the three types of effective practice in professional development. Although there still are widespread examples of each of the five models of professional development posited by Sparks, professional learning communities bear significant resemblance to the school-based curriculum committees of Newlon’s Denver Plan of the 1920s, signaling another cycle of reform that sees teachers and their professional development as the key to school improvement, rather than a barrier to progress.

## TEACHER EMPOWERMENT

---

*Teacher empowerment* is a concept with many contested meanings, but the term initially took hold as an antidote to the dominant teacher-as-clerk model. It signaled an attempt by school people to professionalize teaching in the sense of recognizing teachers as experts in the craft and content of teaching, teachers as best able to generate and uphold teaching standards, teachers as most responsible for classroom practice. Teacher empowerment is meant as well to protect teachers from interference from mindless bureaucrats, ambitious politicians, and ideologues of every stripe.

Of course, this does not settle the matter, because teaching in a democracy does indeed require dialogue, conversation, and contestation between teachers, parents, communities, politicians, and the widest possible public. Teachers in this circumstance cannot be entirely free agents, doing their thing in a bubble—imagine, for example, a racist teacher or a homophobic teacher. Still, the idea of teachers struggling not so much for absolute autonomy, but for recognition, dignity, and the value of their unique position and knowledge—in the mix with all the other actors—is what teacher empowerment has generally come to signify.

Teacher empowerment requires teachers to commit to the task of continuous experimentation, investigation, inquiry, and study, to negotiating the troubled waters of teaching, to growing and

learning for an entire lifetime in the classroom. It requires that teachers create a space for problem posing and problem solving, historical and theoretical considerations, storytelling, and critical reflection.

Too often teachers have experienced little in their own training beyond a few courses in educational philosophy and psychology, the history of education, then the methods of teaching, and finally a synthesizing moment when everything is theoretically brought together in student teaching. Critics contend that this approach structures the separation of thought from action, rips one from another, and walls the mind off from the body, weakening both. From this perspective, this approach is lazy at best, miseducative always. But worse, it ignores the humanizing mission of teaching, and the intellectual and ethical heft teachers need to develop if they are to be powerful and wise people in the classroom. Proponents of teacher empowerment argue that the message of the existing curriculum tells teachers what is to be valued and why—it stresses the mindless and the soulless rather than attending to the ethical and intellectual dimensions. It prepares them for life in factory-style schools.

Teacher empowerment, however, assumes that there is no simple technique or linear path that will take teachers to where they need to go, and then allow them to live out settled teaching lives, untroubled and finished. There is no promised land in teaching, just that aching persistent tension between reality and possibility.

Empowered teachers must figure out what they're teaching for and what they're teaching against—against oppression and subjugation, exploitation, unfairness, and unkindness, perhaps, and toward freedom, enlightenment and awareness, wide-awakeness, protection of the weak, cooperation, generosity, compassion, and love.

---

## TEACHER KNOWLEDGE

---

In the late 1970s, the concept of teacher thinking began to appear in the curriculum studies literature. Christopher Clark and Robert Yinger published the first review in the field of teacher thinking, gathering the work of U.S. researchers, work that, for the most part, originated conceptually with the scholarship of N. L. Gage. Researchers worked from a cognitive information-processing approach that was concerned with teacher judgment, decision making, and planning and focused on research that studied the psychological aspects of thinking in the areas of teacher planning, teacher judgment, teacher interactive decision making, and teachers' implicit theories or perspectives.

Around the same time, another focus, teacher deliberation, emerged from Joseph Schwab's understanding of curriculum. Initially, F. Michael Connelly focused on teacher deliberation, but he, with Freema Elbaz-Luwisch, developed research on what they called teacher practical knowledge. For them, teacher practical knowledge emerged from a view of a teacher as an active agent deploying practical knowledge in teaching and planning for teaching. They described teacher thought as prescriptive toward action and as occurring through deliberation, a process on which there has been some research. However, they noted little research on the nature of the practical knowledge with which each teacher does his or her thinking. They defined teacher practical knowledge in three ways: (1) as having content; (2) as being oriented to situations, to the personal, to the social, to experience, and to theory; and (3) as structured in rules, practical principles, and images.

As D. Jean Clandinin began work with them, the focus became teachers' personal practical

knowledge defined as the convictions and meanings, conscious or unconscious, that have arisen from experience (intimate, social, and traditional) and that are expressed in a person's practices. They drew on Michael Polanyi's argument that knowledge has a subjective, personal character, Mark Johnson's view of knowledge as embodied and expressed socially, and John Dewey's idea that knowledge and knowing are dialectical combinations of subject and object, of the cultural and the individual.

Eventually, the research focused on narrative ways of understanding teacher knowledge that attended to the dialectical relationship between teachers' personal practical knowledge, itself a dialectic between the personal and social in each teachers' knowledge and between the personal and the social of the contexts in which teachers lived and worked. The social of school, school contexts, was conceptualized through the metaphor of a professional knowledge landscape, a metaphor that created a discourse of space, place, and time. Teachers' knowledge landscapes were seen as both intellectual and moral landscapes and were understood as narratively constructed with historical, moral, emotional, and aesthetic dimensions. The landscape metaphor drew attention to the relational, temporal, and shifting nature of school contexts.

Research programs in these two distinct but related areas, that is, teacher thinking and teacher knowledge, eventually came together into one of the most intellectually vibrant research areas in curriculum studies in the late 1900s and early 2000s. By the mid-1990s, Gary Fenstermacher reviewed the literature in the area of teacher knowledge, noting that there were three strands of research: one with origins in the work of Connelly, Elbaz, and Clandinin, a second with origins in the work of Donald Schön, and a third with origins in the work of Lee Shulman. Schön, also working from a Deweyan view of experience, described practitioner knowledge as tacit, implicit in each person's patterns of action and as in each person's action. Shulman viewed teacher knowledge in terms of pedagogical content knowledge, knowledge that went beyond subject matter content to embody aspects of content relevant to its teachability.

As the work on teacher knowledge developed, it was influenced by philosophical work on the

nature of knowledge being undertaken by feminist scholars such as Mary Belenky, Blythe Clinchy, Nancy Goldberger, and Jill Tarule and Lorraine Code, and by Deweyan philosophers such as Mark Johnson and others. In the curriculum field, educational philosophers such as Maxine Greene and Nel Noddings and curriculum theorists such as Sandra Hollingsworth and Janet Miller shaped the ways teacher knowledge was being conceptualized. As teacher knowledge came to be seen as embodied, relational, context-specific, and experiential and as lived out and shaped in and by contexts, questions about the relationship of theory and practice were explored in new ways in curriculum studies.

The most recent work on teacher knowledge has been taken up by individuals interested in the storied nature of teacher knowledge. As links were made between narrative conceptions of teacher knowledge and teacher identity, other recent work focused more directly on teacher identity with a less direct focus on teacher knowledge.

*D. Jean Clandinin*

## TEACHER LORE RESEARCH

---

Teacher lore research is a form of narrative inquiry based on rich teaching accounts written by or about the teacher involved. Through these contextualized accounts, collectors of teacher lore hold that teachers will discover their own theory

through sharing their own voices as they reveal their beliefs, understandings, and knowledge. Most of the teaching stories are true; some have been fictionalized. Often, education scholars and policy makers are blind to the expertise of individual teachers, making sweeping decisions with little attention given to those teachers and students most directly affected by mandates. Within the field of curriculum studies, which seeks to reveal and analyze the complexities of curricular decision making, teacher lore research provides a way for the voices of practitioners themselves—those who engage in teaching day to day—to be part of the ongoing professional conversation regarding what it means to teach and what it means to be well educated.

Teacher lore is a practical form of writing reflectively about critical incidents in the teaching and learning of individual teachers. Editors of teacher lore volumes, including William Schubert and William Ayers, Gretchen Schwarz and Joye Alberts, and Carol Witherell and Nel Noddings, hold that teachers think deeply about the myriad of classroom decisions they make. Though not theoretical in the traditional sense of relying on professional literature as the basis for decision making, teachers form theory through examining the experiences of themselves and other teachers.

Most curriculum writers who collect teacher lore find authenticity in teachers' own stories, though Schwarz and Alberts extend the general concept to include fictional accounts from novels and films. All edited volumes of teacher lore posit a belief that teachers' stories, richly told, are an appropriate basis for grassroots reform of education.

Situated within the reconceptualization of the curriculum field, teacher lore research gives voice to teachers. Part of the negative reaction to increasing demands to quantify educational goals and outcomes following publication of *A Nation at Risk*, the teacher lore movement respects the voices of practitioners and seeks to honor their experiences, blurring the commonly touted dichotomy between theory and practice. Also in response to academics criticizing the apparent lack of theoretical foundation for individual teachers' decision-making processes, teacher lore researchers see their work as a way to respect teacher voices and recognize that building teaching theory is personal rather than academic, practical rather than distant.

Multiple voices of teachers, across time, geographic distance, PreK–16 teaching level, and content area, are valued.

As long as there have been teachers there have been teaching stories, but teacher lore as an accepted narrative research method came from a combination of the rise of teacher research as a form of systematic inquiry and Donald Schön's advocacy of reflective practice, calling for teachers to write about teaching decisions and events as a basis for deliberative reflection. As a separate research method, teacher lore became popular during the late 1980s continuing through the 1990s.

Teacher lore research is also connected directly to Elliot Eisner's notion of *educational connoisseurship*, in which teachers analyze decision making from an aesthetic viewpoint, rather than a means–ends or technical–rational viewpoint. Also related to teacher lore research is the use of case studies as vehicles for preservice and inservice teachers to examine practice. However, there is a clear distinction between teacher lore and case study, with the former including richly contextualized detail and the latter eschewing context as much as possible. One purpose of teacher lore is to provide thickly described context as a means to increasing the reader's understanding of a particular event, whereas a case study depersonalizes a described event to make it apply to as wide an audience of teachers as possible.

Teacher lore research is also related to teaching memoirs, such as those by William Ayers, Jane Tompkins, and Esme Raji Codell, with the difference lying in a matter of focus; teacher lore research is usually based on a single significant event or related series of events, whereas a teaching memoir is a more detailed chronicle over an extended period. It is most common for teacher lore researchers to collect writings of many individual teachers and to organize them topically or thematically. For example, aiming at an audience of preservice and first-year teachers, Pearl Rock Kane collected teacher lore pieces from many experienced teachers, each of whom wrote and reflected on a critical incident from their first year of teaching.

Schwarz and Alberts, by asking teachers to write about an earlier event and to write about what they have learned from writing their teacher lore pieces, reconnect smoothly with teacher lore

research by making the analysis itself visible to the reader. This systematic analysis can also be seen in more recent publications that no longer claim to be part of teacher lore research, including the National Writing Project's (NWP) work in collecting vignettes from teacher leaders within that organization. Ann Lieberman and Linda Friedrich have begun analyzing the vignettes as a way to understand better the capacity building effects of NWP activity for individual teachers engaging in leadership activities across their professional lives.

Teacher lore research in and of itself is rare at this time. The current climate of standardization, accountability, and scientific evaluation has gone far beyond that experienced by teacher during the height of teacher lore research. Teacher lore is now included in the larger fields of teacher research or narrative research.

## TEACHER-PROOF CURRICULUM

---

During the 1960s and early 1970s, curriculum reform efforts in many English-speaking countries led to the development of the “teacher-proof curriculum” as a central component of reform. As the term *teacher-proof* suggests, the aim was to minimize the teacher's control on curriculum development by creating a firm relationship among educational objectives, curriculum content, and

assessment tools. The notion of the *teacher-proof curriculum* is a course of studies well structured, firmly integrated, well supported by rich and motivating materials such that teachers could not stand in the way of a direct transaction between the learner, the student, and the learning recourses—the curriculum package.

The teacher-proof curriculum was designed by specialized curriculum experts, removed from the local school community, in a cookbook fashion so that any teacher who uses the curriculum will have the same results. In the teacher-proof curriculum, the goals (why), content (what), and methods (how) of instruction were prescribed for teachers within self-contained sequenced lessons. Further, educational objectives, curriculum content, and assessment tools were all packaged in a set of curriculum materials considered to be immune to teacher practice and belief. In this context, teachers and the local school community were to play a secondary role to those of national educational administrators and the curriculum experts: The aim was the accomplishment of high levels of commitment between the conception and practice of curriculum reform. Questions of curriculum change became the issues of managing the dissemination and control. The curriculum development process was seen as a technical exercise involving the setting of objectives and the measuring of outcomes, thus narrowing education to being a limited and technical activity. High-stakes tests were used as a measure of teacher effectiveness.

Similarly, the reform efforts on a developing discipline-based national curriculum in English-speaking countries during the 1960s and early 1970s has also reflected a somewhat centralized approach to curriculum change with the explicit aim of having a codified curriculum producing a new social order reflective of dominant groups. Curriculum control was a key subtext of these reform efforts. The endorsement of state-mandated high-stakes testing by policy makers and politicians legitimated the specification of instructional objectives and methods within the teacher-proof curriculum and resulted in the commodification of teachers' instructional practices.

Some proponents of the teacher-proof curriculum argued that teachers were so underprepared in their subjects that the curriculum must do everything for them. Thus, it must tell them

exactly what to do, when to do it, and in what order. This view of curriculum assumed that there is a right way to organize and teach the curriculum, and that, if teachers have a curriculum that represents this right way, students will learn a subject matter well.

These curriculum models were framed by a fairly rigid set of assumptions grounded in the modernist education system. In other words, the curriculum development was set within a vision of schooling that is highly regulated in time and space, and that views knowledge as rational, linear, and arranged in separate and distinctive disciplines.

Research on curriculum development during the 1970s and early 1980s revealed the difficulty in achieving the goals of teacher-proof curriculum packages because the reform efforts failed to account for the temporal, social, economic, and cultural factors that define and guide the possibilities for change in specific school communities.

In the late 1970s and 1980s, curriculum theorists began to advocate the central role of teachers in curriculum change and development and the need for teachers to own aspects of the changes that were sought. The emergence of new approaches to curriculum development, such as school-based curriculum development, reflective practice, and action research began to promote a trend toward locating members of school communities and teachers at the center of curriculum reform efforts. For some proponents of the new changes, the reforms represented a democratization of curriculum development, in which the teachers were empowered in the processes of curriculum development.

## TEACHER–PUPIL PLANNING

---

Teacher–pupil planning represented a widespread curricular-instructional practice of teachers who were attempting to embody general principles of progressive education and democracy in the classroom. Although teacher–pupil planning was never codified into a formal, instructional methodology, the practice was used at both the elementary, middle, and secondary school levels and, along with resource units and a fused core curriculum, proved quite popular among progressive high schools of the 1930s and 1940s. To view the activity as an example of the child-centered curriculum movement would be a disservice to the concept as would describing teacher–pupil planning as a component of the “activity curriculum.” Although all of these terms have been used to portray teacher–pupil planning, the practice stressed other concepts and was developed as a way to reconcile specific curricular dilemmas of progressive education—namely, the interests and needs of the students and the building of community.

Although teacher–pupil planning ultimately resulted in the development of curricular activities, its origins arose more as a way to reconcile the balance between student needs and interests as the sources for selecting curricular experiences. Defining democracy in the classroom as a setting where experiences would be determined by both the (shared) interests of the students along with the perceived (real) personal/social needs of the individual, teacher–pupil planning served as a way to develop a classroom atmosphere where youth could build meaningful relationships with adults (the teachers). Attention was devoted to ways to assist teachers to better anticipate student interests and needs, and methods to introduce “cooperative” classroom practices.

Although intended as a method to select course content, teacher–pupil planning entailed much more: providing motivation for teachers and students and encouraging both to extend the range of their shared interests and values. Over time, criteria evolved as both students and their teachers became increasingly sophisticated at cooperative work. This did not mean that teachers abdicated their responsibilities and allowed students to pursue questionable topics, as critics have charged.

Quite the contrary, teachers were expected to be more conscientious than they typically had been in traditional instructional settings and were responsible for noting curricular possibilities that otherwise would have been overlooked. In what proved to be the most comprehensive treatment of the practice, H. H. Giles describes seven characteristics of this curricular-pedagogical method: democracy, use of scientific method, change as a constant factor, creativity, individualization, socialization, and organization through a problem-oriented approach.

Teacher–pupil planning involved the following practices: Before a first class meeting, teachers would conduct a preliminary survey of pupils’ backgrounds. They would review cumulative files to learn about abilities and interests as well as about past academic experience, and they discuss the previous years’ work with a view toward program continuity. Preplanning involved carefully anticipating possible topics and projects for study, surveying available instructional materials, and devising ways to evaluate the completed work. Larger school aims were always kept in mind as were students’ individual needs. All of this work took place outside of the classroom and was often quite time consuming. A 2-month unit might take 2 full weeks to plan as time was spent identifying salient topics (often the most difficult problem), assigning group and individual projects, deciding on common experiences, and determining how ideas would be brought together, shared, and evaluated. During the process, revisions would be made as needed. Planning was as much a part of the learning experience of students as was the execution and evaluation of the designs themselves, each a component of intelligence as a method for reflective thinking.

One insightful description of teacher–pupil planning is described in an anecdote told by one of the Ohio State University School core teachers, William Van Til, who described a talk given by Giles on the method. A critical question was posed by a member of the audience who doubted the wisdom of involving students in planning and distrusted their ability to make important educational decisions. When Giles was asked which was more important in teacher–pupil planning—the teacher or the pupil—Giles’s reply was “the hyphen.” Just as core curriculum represented much more than

the act of merging content, teacher–pupil planning as a form of instructional discourse went far beyond a series of teacher and pupil choices. The hyphen represented a working conception of cooperation and democracy in the classroom.

## TEACHERS AS CURRICULUM MAKERS

---

Teachers as curriculum makers is an image that acknowledges the teacher as a holder, user, and producer of knowledge, a self-directed individual who takes the curriculum as given and negotiates it in active relationship with students to address their needs as learners and, to the extent possible, meet the requirements outlined in stated curriculum documents. Unfortunately, the fields of curriculum and teaching have evolved independent of one another in much the same way as Division B (Curriculum) and Division K (Teaching) of the American Educational Research Association (AERA) have developed separately. A similar structural and relational divide is apparent within teacher education and curriculum faculties lodged in departments and colleges of education. Disconnects between the knower and the known have abounded in the educational enterprise as historically conceived. Yet, the fields of curriculum and teaching might not be so estranged if the teacher as curriculum maker image was adopted. After briefly describing the background, this entry addresses the conceptualization and the recent scholarship of teachers as curriculum makers.

### Background

The teacher as curriculum maker conceptualization was first introduced to the field of education in 1992 by Jean Clandinin and Michael Connelly. But the seed of the idea initially took root in an earlier book authored by Connelly and Clandinin, which was primarily written for a teacher audience. Clandinin and Connelly drew on many sources in developing the image: educational history—work involving stability and change, educational philosophy—Dewey’s theory concerning the ends and means of education, and educational leadership, which, like other facets of the literature, positioned teachers as mediators between curriculum documents and student outcomes. Also, the agency Ralph Tyler afforded teachers played a role, as did Joseph Schwab’s “practical,” most especially his curriculum commonplaces, which upheld the centrality of the teacher in curriculum deliberations and provided *raison d’être* for the teacher as curriculum maker image. Connelly and Clandinin’s programmatic research, which has sought to understand teachers’ knowledge in their own terms and in context, additionally informed the image’s creation.

The teacher as curriculum maker image works from the assumption that a classroom space exists within which teachers and students negotiate curriculum unhampered by, though not oblivious to, others’ mandates and desires. That space, however, is discretionary, which means that teachers and students need to act as moving forces and seize the possibilities inherent in it. Also, opportunities for maneuvering within the classroom space are influenced by others—for example, fellow teachers, administrators, school district personnel, staff developers, parents, and policy makers—who also have a shaping effect on classroom experiences. In the space teachers and students mutually carve out, distinctions between the knower and the known fade. So, too, do the means and ends of education merge. As active agents, teachers work as minded professionals guided by their own sensibilities and practical ways of knowing. In a like manner, students actively participate as knowers of their own experiences and producers of their own knowledge, not simply users of codified knowledge, which their teachers receive via a metaphorical conduit and correspondingly transmit to them.

### Conceptualization

In Clandinin and Connelly's view, curriculum is more than a planned document or a program of study external to teachers. It is what teachers and students live as they interact with one another, although curriculum guides, textbooks, and other materials play a part. The concept of the teacher as curriculum maker calls attention to the primacy of the teacher in organizing, planning, and orchestrating these interactions because only the teacher is situated at the epicenter of the curricular exchange and encounters students face-to-face. Thus, curriculum is what happens—what becomes instantiated—in the moments when teaching and learning fuse. Hence, what teachers hold and express as part of their knowing—that is, what they reflect on, build theories about, view as significant, negotiate meanings for, and act upon—automatically informs their pedagogical interactions with students. Similarly, students' prior experiences and future desires form part of the curricular mix, as do their relationships with fellow learners. Hence, when a teacher as curriculum maker teaches students, the teacher brings forward his or her knowledge about himself or herself as a teacher, the course content, the milieu in its endless complexity, and his or her knowing of the person at a particular place and time within the student's learning experience. In this space, practical and formal ways of knowing mingle, producing new iterations of practical knowledge that both the teacher and students will call forth in future situations. In this way, the teacher as curriculum maker image resonates with the organic connections between curriculum and life. In engaging curriculum, meaning becomes reconstructed through reflection and leads to growth by teachers and students. Indeed, the teacher as curriculum maker image fuels the very essence of the Deweyan idea of education as reconstruction without end.

The teacher as curriculum maker conceptualization offers a viable alternative to the dominant plot line of teacher as curriculum implementer, an image Clandinin and Connelly also captured. In that conceptualization, the teacher uses other people's knowledge and, in a technical rational way, installs a curriculum/curriculum package designed by others. In short, the image of teacher as curriculum implementer treats teachers as

functionaries who are totally reliant on state and national imperatives. In this technical view of the teacher, fidelity to others' directives reigns supreme as Cheryl Craig has demonstrated in her research studies.

### Recent Scholarship

The teacher as curriculum maker image more recently has been advanced by Cheryl Craig and Vicki Ross. They focused on how the image became cultivated in the aftermath of Schwab's "practical." Craig and Ross particularly traced what happened to the research lines of four of Schwab's prominent students: Elliot Eisner, Seymour Fox, Lee Shulman, and Michael Connelly. Although Eisner's work in the areas of art education, curriculum studies, and school reform did not involve direct contact with teachers, his locating of his research at the intersection where teaching and curriculum meet allowed him and some of his students—for instance, Gail McCutcheon and James Henderson—to make significant contributions to the teacher-as-curriculum maker image. As for Fox, he lived his version of "the practical" with others at the Hebrew University of Jerusalem. Consequently, a rich related literature developed in Hebrew and English. Included in this work is the research of Miriam Ben-Peretz, Freema Elbaz-Luwisch, and Lily Orland-Barak. Meanwhile, Shulman's scholarship involved the conceptualization of pedagogical content knowledge, the wisdom of practice and the use of case studies in teaching and teacher education, all of which reflect a version of the teacher as curriculum maker approach. Pamela Grossman, Anna Richert, and Suzanne Wilson, each of whom studied with Shulman, also took up related research interests. In their focus on pedagogical content knowledge, these researchers tend to emphasize aspects of teacher knowledge as needing to be developed by teachers and as being better in some than in others, which suggests more of a formal knowledge approach. A subtle contrast between the latter two research lines is the implication in the Clandinin and Connelly work that teachers simply are curriculum makers whose accounts are vital to understanding what currently is happening in schools and classrooms. This is further evident in Clandinin and Connelly's notion of personal practical knowledge. This concept adopts an epistemological stance of teachers as

knowers and approaches schools as practical places comprising the contexts of teaching. The promotion of the use of narrative inquiry, with and by, teachers embraces the knowledge stance of teachers as curriculum makers based on their personal practical knowledge. Students of Clandinin and Connelly—Carola Conle, Ming Fang He, Janice Huber, and Margaret Olson, for example—also nurture the teacher as curriculum maker image through Conle’s explorations of narrative inquiry as a form of teacher development, He’s approach to culture and multiculturalism within the context of people’s lives, Huber’s inquiries into the nested nature of teacher-student-researcher relationships, and Olson’s account of curriculum as a “multistoried process.” Olson and Craig’s coauthored works have further illustrated how the teacher as curriculum maker develops his or her narrative authority in knowledge communities. Finally, Clandinin and colleagues’ recent book, with an afterword by Stefinee Pinnegar, brings to light the complexities that emerge at the interstices where teaching, learning, and public policy meet by illuminating the interweaving of children’s and teachers’ lives.

In addition to the direct connections relating to the Eisner, Fox, Shulman, and Connelly-Clandinin lines, Craig and Ross noted that Schwab’s “practical” left a major imprint on other parts of the field as well. The teacher as curriculum maker image is present in the self-study of teaching and teacher education, action research, case study research, and reflective portfolio making literatures, among other related fields of inquiry (i.e., narrative practices, interdisciplinary studies, teacher work groups, and teachers helping teacher). As Connelly and Shijing Xu averred in the most recent curriculum handbook, the curriculum field no longer involves two strands of inquiry: Those who moved toward theory and those who moved toward practice as Phillip Jackson asserted in the previous volume of the handbook. Rather, an “in-between” literature has emerged in the content-specific and teacher-thinking areas as well as in a myriad of AERA special interest groups (SIGs). As can be seen, much of the scholarship pertaining to the teacher as curriculum maker image is of this in-between variety. It begins in practice, draws on theory, and uses context to make sense of both.

## TEACHERS AS INTELLECTUALS

---

Henry Giroux’s collection of essays *Teachers as Intellectuals: Toward a Critical Pedagogy of Learning* represents the evolving arc of radical and critical educators and theorists’ efforts to critique and affirm the essential role and agency of teachers and students in the struggle to create an emancipatory education and practice grounded in democratic principles of justice and equality. These essays, influenced by cultural and social reproduction theory and theoretical perspectives of radical and critical theorists such as Paulo Freire, Antonio Gramsci, Stanley Aronowitz, Peter McLaren, and Ira Shor, reflect a critical pedagogy emphasizing the importance of individuals as social actors and change agents. Giroux was among the first theorists to develop and define the

term *critical theory* as a vehicle for moving beyond the prescribed vision of schools as mainly sites of reproduction of social inequities, to one of schools as important contradictory sites within which teachers and students choose to accommodate or resist the traditional and oppressive language and structure of schools. An important feature of these essays is Giroux's rejection of the traditional view of schools, curriculum, teaching, and learning as neutral and apolitical processes set apart from the larger social contexts in which they are constructed and negotiated. Rather, Giroux argues that schools are public spheres reflecting the larger society in which social, cultural, and political struggles are simultaneously reproduced, resisted, and transformed in an ongoing struggle of democratization. As a social, cultural, and political space, schools become a place in which teachers and students participate in a viable democratic process of resistance; an emancipatory practice grounded in student empowerment.

Perhaps the most significant aspect of this book is its conceptualization of teachers as *transformative intellectuals*. This portrayal becomes particularly compelling in light of current education reform models that, by defining education as training, contribute to the deskilling and devaluing of teachers through a limited curriculum and high-stakes testing.

The use of the term *intellectual* as it applies to teachers differs from traditional and elitist definitions of intellectualism. As intellectuals, Giroux's teachers are viewed as agents and advocates to develop more democratic and inclusive pedagogy, that address moral and ethical questions about the purpose of education as an authentic and evolving democratic enterprise. This examination of the emancipatory, intellectual teacher in collaboration with empowered students challenges traditional views of teaching and learning as technical and decontextualized. The practices of critical educators and teacher intellectuals reflect a perspective that rejects the notion of education as a value-neutral process, thus making transparent the political and structural dimensions of schools as places of social production and reproduction. Schools are recognized as political sites, and the intellectual labor of teachers must include speaking and acting in ways to disrupt and remap hegemonic arrangements. For Giroux, such a remapping demands a

collective and critical interrogation of historically oppressive structures embedded within the purposes and practices of schools as well as the larger society. This critical practice is grounded in a living vision of schools as democratic public spheres linked to the larger struggle against various forms of political, economic, social, and pedagogical oppression. In this enterprise, a language of critique is combined with a language of possibility and hope, providing a blueprint for revisioning schools as one of many contested sites of democratic possibility, and teachers and students as indispensable agents in the struggle to create the conditions necessary for critical consciousness.

The strength of these essays is also a critique: Both teachers and students are charged with the primary responsibility of examining and questioning those pedagogical, curricular, political, economic, social structures and practices in which they participate, *and* for developing strategies to resist and change these oppressive structures and practices. Teachers are viewed not as mere performers held captive by the schools in the reproduction of official knowledge and practices; rather, they are free to engage in a critical and reflective practice in which new knowledge may be produced both with and in the service of their students. The challenges lay in the consideration of how teachers can become and remain transformative intellectuals within the oppressive and anti-intellectual structures of schools.

## TEACHERS COLLEGE COLLECTIVE OF CURRICULUM PROFESSORS

---

Teachers College at Columbia University has earned a reputation in the past century as a national leader

in curriculum studies. During the early to mid-20th century, the institution resisted forming a dominant philosophic orientation or preferred epistemology. Widely recognized for its promotion of variations of progressive (experimentalist) education, fostered by the contributions of John Dewey, faculty members at Teachers College simultaneously advanced the “scientific” approaches to education advanced by E. L. Thorndike as well as the essentialist platform of W. C. Bagley and I. L. Kandel. The use of laboratory schools for experimentation with curriculum and instruction was widely emulated in other teacher preparation programs. By mid-century, Hollis Caswell promoted focus on school reform with the support of Alice Miel and Arthur Wells Foshay, and Florence Stratemeyer and the life adjustment curriculum offered an approach that combined elements of former oppositional perspectives at Teachers College. In the 1960s and 1970s, the insights offered by existential and personal explorations of curriculum, represented in the work of Maxine Greene and Dwayne Huebner, offered novel approaches to curriculum studies incorporating new philosophic orientations and the language of aesthetics.

A model of curriculum that had compatibility to the instructional models promoted by Thorndike was provided by David Snedden who championed the expansion of industrial training for adolescents through vocational schools and the inclusion of manual arts preparation introduced in the latter elementary grades. Snedden suggested that a curriculum be directed to production (vocation) and consumption (liberal arts), subdivided into specific skills (performance practices) and then again into a grouping (strands) of specific objectives. Snedden divided culture into seven divisions, each with its own set of values and knowledge. The most important form in U.S. society was vocational. Other cultural forms Snedden claimed merit a place in the curriculum are morality (interpersonal relationships), civics, religion, physical activity, eutenics (aesthetic appreciation), and humanities. Snedden contended social utility dictated the value of a cultural form to the curriculum, adapted then to the social contribution that a learner is likely to provide. Thus, curriculum assisted in promoting social classes based on economic production, recognizing the purposes of education are as varied as

the social functions individuals are asked to perform. Division of disciplines was efficient and effective education.

From the college’s inception, Dean J. E. Russell envisioned experimental laboratory schools to research and demonstrate cutting-edge curriculum and instructional models. The earliest association was with Horace Mann School, founded in 1887. A private tuition coeducational institution, Horace Mann attracted children of the professional classes and the expectation from parents was that the school would not treat their offspring as laboratory subjects. In an effort to establish a laboratory school representative of a typical urban population, the Speyer School was established. A tuition-free institution, the curriculum was envisioned as integrating traditional academic subjects with industrial arts. Frederick Bonser and Lois Coffey Mossman were recruited to establish the industrial arts curriculum for the elementary grades. The curriculum and the book that resulted from their work at Speyer became a standard reference on industrial arts training in the elementary schools, emphasizing Mossman’s insistence that no skill be taught without resulting in the production of a final product. The Speyer experiment, however, did not capture the interest of leading Teachers College faculty and was abandoned when Lincoln School was established in 1917.

Russell recruited Patty Smith Hill specifically to implement innovations in the early childhood curriculum at Speyer School in 1905. In 1910, Hill became head of the college’s department of kindergarten education and full professor in 1922. Hill’s ideas on a curriculum of play and creative expression for kindergarten were resisted at Speyer but did find acceptance at Horace Mann School. Instructional artifacts used by Hill became standard progressive practices across the nation. With psychologist Agnes Rogers, Hill developed a “Tentative Inventory of Habits,” 84 desired learned behaviors to direct kindergarten curriculum and instruction, which gained Hill an international reputation in early childhood curriculum.

A third laboratory school was established with Teachers College in 1917. Lincoln School was intended as a demonstration site for progressive curriculum and instruction, emphasizing thematic units of work and student collaboration. Located in the high-rent district, Lincoln School was a

private tuition institution where teacher-researchers conducted studies of their innovations and shared their experiences in national journals and the school's publishing house. The emphasis on "modern" was, however, often closer to Snedden's conception of social utility with lessons relating to industrial and financial operations and emphasis on science and mathematics. Thus, Lincoln School, with conflicting purposes and interests, combined with Horace Mann School and then a re-configured approach that included working with a cluster of schools was put in place in the 1950s.

An alternative curriculum for teacher preparation, New College, was also designed and implemented in the 1930s, directed by Thomas Alexander and centered on problem solving in the "persistent problems of living." The intent was to produce teachers with a progressive orientation who would advance social reform. Given Alexander's specialization in European education, foreign study was a requisite element of the program as was spending at least one summer on a farm in the South to promote communal living. Students were also required to gain work experience by obtaining a job locally and then reflect on what was learned from this experience. Institutional interest in the New College faded, and the program was discontinued by the end of the decade.

William Heard Kilpatrick became a leading voice for progressive education through a popular curricular innovation and an equally compelling personality. In 1918, Kilpatrick produced a modest, accessible, Dewey-inspired innovation in curriculum and instruction. "The Project Method" was a thematic unit centered on student interests that addressed cognitive, affective, and physical development of learners through group collaboration on a shared social project. Adapting Dewey's curricular and instructional proposals, Kilpatrick promoted a curriculum responsive to children's interests but also contributing to social improvement, two important variations of progressivism at Teachers College.

Thomas Briggs, who earned his doctorate at Teachers College and conducted initial studies on the value of the formal teaching of grammar, was a member of the reviewing committee for the *Cardinal Principles of Secondary Education* and became a leading proponent for reform of the junior high and secondary school curriculum

as a general studies program for adult participation in contemporary society. Harold Rugg came to the faculty from the University of Illinois having worked on student evaluation, but shifted to consideration of the child-centered curriculum and how a curriculum can bridge student interests with contemporary social issues. George Counts and Jesse Newlon developed a social reconstructionist proposal that teachers be agents for social change and that schools be forums for students to consider current important social issues.

L. Thomas Hopkins came to Teachers College as a faculty member and developed a line of curriculum work that emphasized individuality, collaboration, and noncoercion. Learning, for Hopkins, was "organistic" or "interactive." Education fostered awareness that the world presents problems that demand intellectual response. Teachers guided the interests of the child, helping forge an intelligent crossing to a new "integration," selecting curricular experiences that meet both the interests of the child and the social needs of the community. In considering how the learner can be matched to the problems of the social order, Hopkins suggested attention be paid to the developmental level of the student, introducing instruction that increases democratic participation.

As an alternative to the experientialist enthusiasm evident at Teachers College, Bagley offered a proposal that called for the revival of traditional academic studies and was the main author of an "essentialist" platform that directly confronted progressive reformers. Recruited by Russell to Teachers College in 1917, Bagley declared young people are best served when educated in the enduring lessons of the culture; education reflects the wisdom and knowledge of the past—it does not confront the present or speculate on the future. The curricular mission was the culturally grounded, independent social contributor. Working on assumption that human differentiation is not as significant as the characteristics that humans share, Bagley asserted that a core cultural knowledge of social essentials should be determined and imparted to students, differentiating the curriculum only by adapting instruction. Bagley reminded educators that success is the result of hard work and that self-discipline is necessary to undertake these arduous tasks. So, for youth, the formation of habit through

drill, repetition, and discipline may, in the short term, be distasteful, but produces a lifelong regimen of productive habits. A lifelong colleague of Bagley at Teachers College, Kandel was a pioneer in the study of comparative educational systems with specialization in European schooling. Kandel shared Bagley's concerns that vocationalism led to social training and that progressive education was too focused on child development to ensure the learner is provided with induction to the wisdom and knowledge available through cultural studies.

Caswell returned to Teachers College in 1938, where he had earned his doctorate a decade previous, having established his reputation as a leader in curriculum field research and consultation for his extensive, detailed production of curriculum surveys throughout the South. His scholarship on curriculum thought was also well-attested in co-authoring the *Curriculum Development* with Doak Campbell, a state-of-the-art representation of curriculum studies. Caswell was interested in the improvement of curriculum that was responsive to a situation and could be sustained in practice. This was to be done by first documenting the present curriculum, then collaborating with various stakeholders to determine what improvements were most likely to be responsive to the various factors identified in the survey. His efforts were to match the intentions of curriculum policy makers with school instruction. Caswell assumed the presidency of Teachers College in 1954; during his presidency, Teachers College established a program to assist schools in Afghanistan and trained and selected volunteers for teaching service in East Africa.

A book edited by Samuel Everett entitled *The Community School* combined elements of both the Snedden and the Dewey traditions. The emphasis of this book was that the curriculum should be constituted of the life experiences in the learner's immediate community. The school was a child's guide into adult participant in the local society. The most influential statement of this life needs curriculum was the publication of *Developing a Curriculum for Modern Living* by Florence Stratemeyer, Hamden Forkner, and Margaret McKim in 1947. Stratemeyer, a member of the faculty at Teachers College, and her colleagues assembled a curriculum manual for promoting a life needs education, contending that it brought social relevance to the academic disciplines. The

first requirement of curriculum construction was to understand the learner, not social or vocational demands. Education brings the learner and the demands of modern life together through guided experiences of interest to the learner yet important to effective social functioning. Stratemeyer, Forkner, and McKim isolated the social demands placed on each individual in a democratic society as vocational contribution, use of leisure time, family living, local citizenship, democratic cooperation, and world mindedness.

Miel, professor at Teachers College from 1944 through 1971, promoted democratic leadership and decision making among educators with a particular focus on how to implement curriculum change through open collaboration of stakeholders. She offered an examination of the factors that affect reform effort and retained a focus on working to improve schools rather than offering prescriptions for change. Miel argued development needed to be local, not directed by government or academes with the expectation that teachers will serve as mere conduits for a devised curriculum. Foshay came to Teachers College to work with Caswell, earning his EdD in 1949, and returned in 1957 as an administrator responsible for the direction of a network of experimental schools. Interested initially in practices for school improvement, Foshay's thinking then evolved in the 1970s to fostering individuality and expanding the school curriculum beyond the traditional academic subjects to considerations of values and worth. Like Miel and Foshay, Arno Bellack was also a graduate student during Caswell's tenure at Teachers College and was given a faculty appointment. Bellack researched teacher behavior in classrooms, determining instruction largely followed a "pedagogical cycle," with the teacher initiating a question, generating student response and then affirming or clarifying the response. His systematic observational studies indicated that teachers were more alike than different and there was little room given in the classroom for student initiation of curricular topics.

Huebner and Greene's entry to the faculty at Teachers College signaled new directions for curriculum studies at Teachers College. Huebner, a protégée of Virgil Herrick at the University of Wisconsin, shifted from the empirical study of curriculum implementation to consideration of

philosophy and theology as it informs curriculum thought. Throughout the 1960s and 1970s in published articles and conference presentations, Huebner encouraged colleagues to think about curriculum outside of the conventions of development, implementation, and evaluation, considering the deeper purposes of curriculum meanings. Use of technical and scientific languages limited curriculum studies, Huebner asserted; he encouraged the use of a variety of languages, including aesthetic, poetic, political, and theological discourses to expand curriculum theorizing. Widely acknowledged as a major voice in the “reconceptualizing” of curriculum thought in the 1970s, Huebner continued his scholarship as a professor at Yale Divinity School in 1982.

Greene accepted appointment as a faculty member at Teachers College in 1965, influencing curriculum studies with her study of the contradictions and consistencies that existed in the curriculum of the public school and the development of the individual. Greene’s immersion in the arts and literature as well as existential and phenomenological philosophy served as a unique point of observation of the character of schooling and the identity of the teacher. Her classic work, *The Teacher as Stranger*, published in 1973, pondered the character of the profession and relationships with one’s students. She called for critical awareness, exploring the human condition through the arts, and interacting with others to provoke new possibilities. She shared Huebner’s interest in expanding on purposeful conversations on curriculum meanings.

## TECHNICAL EDUCATION CURRICULUM

---

After years of being considered second rate to traditional academic courses, technical education (formerly called vocational education) now finds itself center stage in the reform of the high school curriculum. According to the U.S. Department of Education, enrollment shot up from 1990 to 2005 by 57%, from 9.6 million students in 1990 to 15.1 million students in 2005. This increase is at least partly the result of the growth of career academies—small schools-within-schools focused on career paths or themes. Designed to make high school more relevant to students, there were 2,500 career academies in the United States by 2007. During the past decade, college-bound and high-achieving students who wouldn’t have considered taking vocational education courses are now moving to them. Likewise, students enrolled in technical education programs, who weren’t expected to take advanced academic classes, are now moving to them. And interestingly enough, the old high school tracking system of taking either college prep or career prep courses is now blurred by students who are crossing over.

Probably the most notable provision of the Career and Technical Education Improvement Act

of 2006 was called the new “programs of study provision.” The law charged states with offering high school students a new kind of career and technical education that would help prepare them for both college and careers, not just for success in entry level occupations.

For many high school students, especially those at risk of dropping out of high school, this mandate was good news. Rather than an alternative to postsecondary education, technical education has become the key to making postsecondary education an achievable goal for all high school students. As professional educators have come to acknowledge, not everyone needs a 4-year college degree to be classified as successful. However, some level of postsecondary education—4-year or 2-year college, apprenticeship, the military, or formal employment training—is almost certainly essential for lasting success.

To enable students to achieve this goal, schools are infusing more demanding academic content into technical education courses. This also means stressing more authentic application in such areas as college preparatory mathematics, science, English, and social studies courses. Focusing just on the technical education curriculum is not enough. Technical education, which traditionally accounted for only 4 or 5 of the 25 courses that students take to earn a high school diploma, has now opened “academic pathways,” which blend academics with technical education. These pathways are where a number of schools are focusing their attention. They are small schools-within-schools and embody the elements of what many in the high school reform movement say all high schools should strive for: high academic standards for all students, small groups of students moving together with the same teachers, and a themed career approach, with students having many connections to the outside world of work. This is perhaps why they are being embraced by many districts looking to break large, comprehensive high schools into smaller learning communities.

Despite the recent explosion in growth, career and technical academies are by no means new: The first was established in Philadelphia in 1965. It was an attempt to find out if career academies could help students from low-income neighborhoods go to college and do well in their careers. In 1994, researcher James Kemple began gathering

data on students from nine such career academies in low-income neighborhoods and at high schools with high dropout rates. Kemple’s ongoing study is considered an excellent investigation, mostly because it contains a control group, and is attempting to resolve the question about whether these programs can affect academic performance and workforce preparation. Results published in 2004, revealed that these nine career academies were having a substantial effect on earnings and employment rates. The academy students had 18% higher earnings than the control group students did 4 years after high school graduation. One thing that the ongoing Kemple study has not been able to show is whether career academies have any effect—positive or negative—on achievement. Both groups of students reported in the 2004 study did graduate at higher rates than the national average for minority students, but as Kemple noted, the students in the control group are finding other opportunities to succeed.

By 2007, the National Academy Foundation was supporting more than 600 academics spread across 40 states that offer students 4-year programs of academic and technical study organized around finance, information technology, or hospitality and tourism. The Ford Partnership for Advanced Studies has been active at more than 150 sites that promote a sequence of courses that integrate academic content with career preparation to advance greater competency in problem solving, critical thinking, communications, and teamwork. Project Lead the Way has introduced academically demanding pre-engineering programs into more than 1,000 high schools throughout the United States.

Career and technical education does not use a one-size-fits-all approach, and it can take various forms according to the needs of school districts, communities, and employers and businesses in those communities. Here are four types commonly found in today’s schools.

1. *Career Academies.* Career academies are smaller learning communities within high schools that focus on career pathways that can lead students to career and to higher education. School counselors in 8th grade help students choose the right pathway for them. High schools in Palm Beach County, Florida, for instance, have 94 career

academies. These academies are based on 16 career clusters as outlined by the U.S. Department of Education.

2. *Part-Time Technical High Schools.* Students at a part-time technical high school attend part time; they go to their home school for general academic classes and extracurricular activities.

3. *Full-Time Technical High Schools.* These schools are usually part-time schools that became full time. They have all the elements of a traditional high school, from a band to a yearbook, and give school diplomas as other schools do. Having the students enroll full time means better integration of academics and career skills. These schools profess to have better achievement scores than the part-time technical schools.

4. *Charter Technical High Schools.* These are few in number but are based on linking parents, community members, and business leaders to focus on the types of career and technical education that should be offered in that community. The charter status gives the district a greater deal of flexibility in its approach and curricular offerings.

Technical education is proving successful in serving students with nontraditional learning styles. Moreover, such curricular innovations as technical education are sparking renewed student interest in critical mathematic and scientific disciplines. These innovations place technical education on the cutting edge of educational reform, as well as helping to firmly establish technical education as the “link” between the needs of employers, the community, and most importantly, today’s students.

## TECHNOLOGY

---

Plato generally uses *epistêmê* (knowledge) and *technê* (art or craft) interchangeably, but in *Philebus*, he divides knowledge into two types: the first addressing education and philosophy and the second addressing production. The fact that technê is teachable is what makes it an epistêmê. From antiquity, the two types of knowledge are inseparable; education and technology will always require each other. Hence, Archimedes’s planetarium, a device that communicated knowledge of heavenly bodies and the gods, was never fully didaskê (instruction), epistêmê, mechanê (mechanics), or technê. Etymologically, *curriculum*, a Latin term for race ground or race course, will always have a technological dimension, even as the infinitive *currere* (to run, traverse) and the related *cursu* reference an experiential dimension. Both terms are first used in their modern sense in the late 16th century: *curriculum* is introduced in 1576 and *technologia* in 1563 in Latin texts of Petrus Ramus, a noted rhetorician at the University of Paris. *Curriculum* referred to the complete course of the seven liberal arts, and *technologia* to the arts of properly arranging, delineating, or systematizing their contents. Indeed, curriculum and technology co-emerge within a specific post-Reformation system of education. *Technology* is first defined in *The New World of English Words* in 1706 (“a Description of Arts, especially the Mechanical”). Although *curriculum* is used through the 17th and 18th centuries in universities such as Glasgow and Leiden, it first appears in English with its Ramist denotation in *A Technological Dictionary*, published in 1846 (“the complete course of studies of a university, school, &c.”). Foucauldian scholars found that bureaucracy is part and parcel of modern schooling, thus technology and curriculum are mutually inherent.

This raises two questions: To what extent is curriculum a technology? And to what extent is technology a curriculum? The first question resolved

over the 18th and 19th centuries through German didactics and object teaching, or what was called general method in the United States. In the late 19th and early 20th centuries, this is coincident with the question of whether education (e.g., didactics, pedagogics) is a science. Franklin Bobbitt's technique of curriculum making, delineated in 1918 in *The Curriculum*, along with standardized testing and the school executive's scientific management systems, epitomized what historian Raymond Callahan described as the "cult of efficiency" in U.S. schooling. The second question, the extent to which technology is a curriculum, is found in Francis Bacon's case for useful knowledge articulated in *The Advancement of Learning* in the early 17th century. Mary Shelley's *Frankenstein* (1818) reiterated the dangers of unchecked optimism in a curriculum of mechanical arts and natural philosophy. Ironically, there was also risk in contempt for the technology curriculum and its creations. This question resolved over the 18th and 19th centuries through the establishment of engineering institutions, the École Polytechnique (1794), Franklin Institute (1824), and Rensselaer School (1824) or lyceum schools in general. Similarly, historically Black colleges, such as Tuskegee Normal and Industrial Institute (1881), schools of industry, manual training centers, home economics, and technical education, offered a technology curriculum for oppressed and working classes in the 19th and early 20th centuries. Historians acknowledge that technological literacies linked to the grammar of the machine were indispensable to ingenuity while germane to forms of alienation documented Karl Marx's *Economic and Philosophic Manuscripts of 1844*. In the name of mass, progressive education in schools, the technology curriculum competed for status and won legitimacy even as labeling, sorting, and tracking reinforced a differentiation of knowledge and skill maintaining conditions for cultural reproduction and preservation of social order. Audiovisual communications faced similar contradictions once specialists shifted from correlating and integrating to developing a media curriculum in the 1960s. Thus, media and technology curriculum formed under suspicion of indoctrination and vocationalism.

Capital investment through the 1920s made school offices as complex as business offices and, although spending on instruction paled next to

administrative expenditures, a wide variety of devices were used in elementary and secondary curricula. Although outlays for curriculum slowed during the Depression, "canned" curriculum, workbooks, film, sound recordings, and radio were introduced into urban schools and shared among classrooms in Canada and the United States. Sidney Pressey, eventually crowned grandfather of computer-assisted instruction, employed the terms *educational engineering* and *educational technology* to describe the changes. In 1933, he called for an industrial revolution in education to transition from handicraft to technological practice. By the late 1950s, *educational technology* was used alternatively with the term *instructional technology* to displace *audiovisual education* and *audiovisual communications* as disciplinary referents and practices. Instruction by machine, learning or teaching with technology, and the automation of curriculum were and continue to be characteristic of reform. Unlike most engineers, Alice Mary Hilton, who laid groundwork for what she called "cyberculture" in 1963, was skeptical of devices for the accumulation of information and maintained that curriculum had yet to be developed for the technological future.

The reconceptualization of curriculum studies in the 1970s and 1980s was a critique of technocratic rationality inasmuch as a reaction to curriculum development. Critical theorists empiricized technology within curriculum while postcritical reconceptualists theorized curriculum without technology. During the past four centuries, various technologies have been instrumental in the separation of curriculum from instruction but, currently, new media and technologies are partially reintegrating the two, narrowing options for postcritical or postreconceptual theorizing. Currently, technologies and technological curricula refer to devices, media, processes, symbols, cyborgs and robots, cyberspace, and knowledge as well as to disciplines, specializations, and the volition animating these things. This raises second-order questions of mediation: How does curriculum mediate technology or in what way is curriculum a medium through which technology propagates? How does technology mediate curriculum or in what way do media propagate curriculum?

## TESTED CURRICULUM

---

The tested curriculum consists of that portion of the curriculum over which a student is tested via national norm-referenced achievement tests, state criteria-referenced tests, and teacher-made tests. Teachers may emphasize the tested curriculum to the detriment of the rest of the curriculum, especially because No Child Left Behind, the federal education act of 2002, requires high-stakes testing of all students Grades 3 to 10. These tests are used to rate the school as "acceptable" or "in need of improvement." Test scores are viewed by many parents, school board members, and politicians as the true assessment of a school's success.

The tested curriculum then becomes the measure of the school's success. Teachers are often encouraged to teach to the goals and objectives of the test rather than to the goals and objectives of the curriculum standards. This becomes the tested curriculum and the focus of the teacher's lessons.

As a result of using the tested curriculum, the elementary school's curriculum may narrow. If only reading and math are tested at third grade, science and social studies may receive only left-over time. The formal curriculum in most school districts consists of much more than a teacher can teach in a year, so some of the curriculum is left behind. On the other hand, the tested curriculum keeps students from being taught teachers' favorite units year after year. Units on dinosaurs, apples, and bats to name a few may be taught repeatedly in the elementary grades without curriculum

standards and the tested curriculum to guide teachers.

Schools and teachers may look at the standards for their curriculum area that they are assigned to teach and compare that with the standards that are assessed in the current assessment plan. The standards that are assessed become the standards that are taught and learned, resulting in the tested curriculum. In upper grades where history, art, and music have specific time periods, the lack of tested curriculum allows the teacher to reflect on the formal curriculum and choose what the teacher believes are the most important topics to focus on.

The purpose of the tests and the tested curriculum is for school improvement, but critics contend that the emphasis has turned into one of devising new tests and turning instructional time into testing time. This becomes apparent in observing the taught curriculum before the test administration. In some classrooms, teachers "drill and kill" students on test items from release tests, and test item format. In other buildings, there may be a tightly controlled tested curriculum taught and assessed via networked computers. At this point, the taught curriculum becomes solely the tested curriculum.

As the media tout schools with high test scores, "A-plus schools," they remark on the focused curriculum in the schools that parallels the tested curriculum. Schools are praised for focusing on core subjects or tested subjects and tested curriculum. To some degree, this is laudable because the standards the tested curriculum is based on reflect key content, issues, and abilities put forth in the curriculum standards. The tested curriculum today includes more than low level rote recall. The current educational reform model claims high standards and assessment that measures high, complex student abilities.

Important decisions are made regarding schooling based on the tested curriculum. Some states approve curriculum changes to align the taught curriculum with the tested curriculum. For example, Georgia approved a change in social studies curriculum to address the massive failures on the social studies state test.

In many school districts, teachers attend professional development activities designed to help them align their taught curriculum with the tested curriculum. Teachers are trained how to align the taught curriculum with what the state expects

students to learn and will test students on. In other words, teachers are trained on how to teach the tested curriculum.

If the tested curriculum comprises curriculum based on high standards, it should result in schools with high student achievement. As with any type of curriculum, how the teacher implements the curriculum makes a difference. If teachers in schools with rising test scores adopt a mastery teaching program where they do not move on until every student has mastered the objective in the tested curriculum, they may shortchange gifted students. In that case, the students who master the objective quickly are left with no challenge. However, a master teacher will use the tested curriculum along with enrichment or extension to meet the needs of all learners.

## TEXTBOOKS

---

Textbooks typically represent manuals of instruction or standard books in particular branches of study as well as powerful and often controversial political and ideological symbols within curriculum studies because they signify particular constructions of reality and particular ways of selecting and organizing information and knowledge. That is to say, the selection of textbook content legitimates and enfranchises some groups' cultural capital while disenfranchising and making illegitimate the "other." In short, textbooks are manufactured articles that play a major role in defining *whose* culture is taught. This entry briefly details the history of textbooks, discusses the debates surrounding textbooks, and describes contemporary textbook publishing and curricular choices.

### History

Textbooks designed for educational purposes were first written in ancient Greece. The contemporary textbook has its roots in the standardization made possible by Johann Gutenberg's printing press. Compulsory schooling and the subsequent growth of common schools in the United States and Europe led to the printing of standardized textbooks for students. Nationalism, patriotism, and Christianity were prominent themes in early U.S. textbooks such as the *New England Primer*, the *American Spelling Book* (also known as the *Blue Backed Speller*), and the *McGuffey Eclectic Readers*. These early 18th- and 19th-century textbooks aimed to implant White Anglo-Saxon Protestant culture by assimilating immigrants from Southern and Eastern Europe through deculturalization. The *New England Primer* prepared readers for submission to authority of the family, the Bible, and the government. Noah Webster wrote the *American Spelling Book*, which was designed to maintain order in a free society, and which replaced the *Primer* and was instrumental in giving the U.S. English language vitality and dignity of its own as well as creating a dominant national culture in the United States through its emphasis on the teaching of republican values, nationalistic songs, honoring the U.S. flag, and participation in patriotic exercises. Calvinist William H. McGuffey compiled the *McGuffey Eclectic Readers*, which were among the first textbooks in the United States that graded textbooks according to their progressive levels of difficulty in reading, science, mathematics, the Great Books (i.e., the Western canon), and history. Rugged individualism, patriarchal hegemony, thrift, honesty, the Protestant work ethic, respect for the flag, the federalist system, and the melting pot theory were among the Puritan principles in this series.

### Debates

Textbooks have undergone increasing debates in recent years with critics claiming that textbooks assert White superiority, mythical untruths, and omissions. Curriculum studies scholars argue that textbooks are shaped by political forces of state adoption boards and ideological pressure groups. Influenced by the mid-20th-century civil rights movement and contemporary immigration

patterns, today's debate about multicultural education ranges from concerns with empowering oppressed people to creating national unity by teaching common cultural values.

Curriculum leaders of the early multicultural movement of the 1960s to 1980s such as James Banks, Christine Sleeter, and Carl Grant are concerned with empowering oppressed people by integrating the history and cultures of dominated groups into public school curricula and textbooks. Contemporary critical multiculturalist scholars, such as Dennis Carlson, Henry Giroux, Michael Apple, Peter McLaren, and Stewart Hall, are concerned with reshaping curricular and textbook content with words and imagery dealing with dominated and immigrant cultures, women, gay people, and people living with disabilities.

For example, history and social studies textbooks in particular underwent scrutiny in the 1960s, 1970s, and 1980s, starting with the 1964 California State Department of Education's report, "The Negro in American History Textbooks." This report was issued by a panel of University of California historians headed by Kenneth Stampp. The panel had been organized in 1963 by the Berkeley, California, chapter of the Congress on Racial Equality (CORE) to analyze U.S. textbooks used in the state's high schools. The panel's report was important because the California State Board of Education selected textbooks that were adopted by local state school systems. The panel pointed out that interracial interactions between Whites and Blacks were portrayed as harmonious and that the history of racial violence was seldom mentioned in textbooks. The panel recommended full treatment of African American history including the early importation and treatment of slaves as well as the recent history of the civil rights movement. Because of the large numbers of sales involved, the textbook industry took notice of the report, and in 1966, the report played an important role in the deliberations of the U.S. House of Representatives investigation of the treatment of minority groups in textbooks. Responding to federal actions, some publishers such as McGraw-Hill and Scott, Foresman published K-12 texts depicting multiethnic settings, White and African American children playing together, and so forth. During this time, however, school districts in the

country were given a choice between the multiethnic and all-White versions.

The textbook industry was charged with Communist infiltration during the cold war. In 1949, the *Educational Reviewer*, a quarterly newsletter with the aim of extracting subversive material from public school textbooks such as Marxism, totalitarianism, and favorable views of the workings of the government of the Soviet Union. In the 1950s, the American Textbook Publishers Institute recommended that states establish public agencies to monitor complaints about textbooks rather than requiring textbook writers to take a loyalty oath as recommended by anti-Communist groups such as the *Educational Reviewer*, the National Council for American Education, the Daughters of the American Revolution, the Sons of the American Revolution, and the Guardians of American Education. Harold Rugg's popular social studies textbook series, *Man and His Changing Society*, encouraged students to look at the U.S. Constitution with a critical eye and as a result was discontinued in 1940 because of right-wing attacks. Among other things, Rugg's critics argued that the series was pro-immigrant (and therefore anti-American) because it celebrated the contributions of immigrant groups and aimed at dispelling stereotypes of immigrant people; Communist (and therefore anticapitalism) because it included information on Marxist critiques of capitalism and challenged big business' fraud and corruption; profeminist (and therefore, antipatriarchal) because it pointed out the economic disadvantages for women and correlated birth rates with poverty statistics.

Contemporary conservative multiculturalists such as William Bennett, Thomas Sobol, Diane Ravitch, and Arthur Schlesinger Jr., argue that different cultural groups should unite around common values and that textbooks should be shaped by the institutions and culture of the United States that are primarily the product of English and European values and that these core values derive from White, Anglo-Saxon Protestant traditions. Science textbooks are the subject of continuing debates and have come under scrutiny from several organizations. The presentation or inclusion of controversial scientific material such as creationism and evolution in public school curriculum has been debated in several court cases.

Contemporary feminists argue that textbooks are often still committed to patriarchal gender roles. In its 1966 founding statement, the National Organization for Women (NOW) called for the full education of women to their potential of human ability. Textbook manufacturers responded by depicting women in a variety of occupations, sports, and gender-integrated vocational courses.

### Contemporary Publishing and Curricular Choices

Contemporary textbook publishing in the United States is a business primarily aimed at large states, in particular, California and Texas. This results from state purchasing controls over the books. The Texas State Board of Education spends in excess of \$600 million annually on its central purchasing of textbooks. Today, several predominant K–12 public school and higher education textbook publishers in the United States include Pearson Education (including such imprints as Addison-Wesley and Prentice Hall), Cengage Learning (formerly Thompson Learning), McGraw Hill, and Houghton Mifflin.

Today, in most U.S. K–12 public schools, a local school board votes on which textbooks to purchase from a selection of books that have been approved by the state department of education. Teachers receive the books to give to the students for each subject. Within higher education, textbooks are chosen by the professor teaching the course or by the college, program, or department as a whole. In the United States, students purchase copies of the assigned textbooks themselves.

Beginning with *A Nation at Risk* (1983) to the current No Child Left Behind Act (2002), mandates for technical control of the curriculum and textbooks through standardization and accountability testing have found a home in the current back-to-basics or accountability movement. Prepackaged sets of curricular materials including textbooks, workbooks, and teacher manuals can be purchased for science, social studies, language arts, foreign language, and mathematics. Often called “systems,” “kits,” or “modules,” these materials are purchased as a total set of standardized material, one that includes statements of objectives, all the curricular content and material needed, prescribed teacher actions and appropriate

student responses, and diagnostic and achievement tests coordinated with the system. Curricular critics of prepackaged curricular systems argue among other things that the teaching profession is deskilled and teacher and student interaction is minimized.

Contemporary technology has changed the site of production of textbooks to include online and digital materials other than the traditional print textbook. Students have access to electronic and pdf books, online tutoring systems, and video lectures.

## THEOLOGICAL RESEARCH

---

There is a long tradition of using theology as a method for curriculum research and as a metaphor for understanding curriculum. Theological research in the curriculum field seeks historical, psychological, and philosophical understandings that will enhance investigations of religion and education, separation of church and government, court rulings on prayer in schools, spirituality and holistic practices in the curriculum, the eschatological dimensions of *currere*, character education, debates about evolution and intelligent design, moral development, values in the classroom, textbook challenges and library controversies, access to religious education, reactions of religious denominations to queer identities, and ethnographic dimensions of religion and spirituality in cultural studies.

Theology (from the Greek *theos*, “God,” and *logos*, “word” or “meaning”) has a variety of interrelated definitions. In pagan antiquity, it referred to a mythological explanation of the ultimate mysteries of the world. The Stoics sought more reasoned knowledge of the “divine” dimension of existence. Aristotle considered theology the “first philosophy” based on an immaterial unmoved mover that he originally considered metaphysics. Contemporary theology often views itself as a reflection on religious experience. David Tracy, however, emphasizes the need to examine truth claims on the basis of rational argument by bracketing religious commitment. His “foundational theology” (also called philosophical or historical theology) seeks to replace earlier fundamentalist theology, which functioned as a form of apologetics. Foundational theology functions analogously to philosophy in its critical role. It seeks to uncover the basic categories with which a systematic theology can be developed. It takes cognizance of the truth that knowledge of reality is available only on the basis of the structure of the particular being who questions it (Martin Heidegger’s *Dasein*). Thus, a wide range of epistemological options are available in contemporary theology, ranging from strict empiricism with structural linguistic analysis (Ludwig Wittgenstein) to neoclassical metaphysics and process philosophy (Alfred North Whitehead) or process theology (Pierre Teilhard de Chardin). Tracy suggests five possible models of foundational theology: orthodox, liberal, neo-orthodox, radical, and revisionist. Mark C. Taylor offers a postmodern mode that he calls “A/Theology”—a theological orientation rooted in an aesthetic of discontinuity and indeterminacy that springs from Jacques Derrida and deconstruction.

Today, theology includes the formal academic study of ontology, cosmology, eschatology, metaphysical grounding of being, historical understandings of the divine, notions of gods and goddesses, hermeneutic analysis of sacred texts and rituals, epistemological understandings of wisdom literatures, notions of existence and time, as well as anti-foundational metaphysics. Theology as an academic discipline helps illuminate these issues. There have been many scholars in the curriculum field who have used theology to understand and advance important issues related not just to religion, spirituality, and culture but also textual interpretation,

schooling practices, and pedagogical philosophies. Some scholars have argued that it is impossible to understand curriculum and schooling historically without the investigation of the theological dimensions of U.S. educational events such as the Olde Deluder Satan Act in Massachusetts in the 1640s, Thomas Jefferson and Benjamin Franklin’s writings on the role of education in a democracy, the Yale report on the “Defense of the Classics” in 1828, Horace Mann and the Common School movement of the 1840s, Jane Addams’s educational and social vision for women and children at Hull House in Chicago in 1889, the progressive education movement of the 20th century, post-*Sputnik* curriculum reforms in the United States from 1958 to 1965, and No Child Left Behind legislation of 2001. Whether accountability programs, testing practices, school structures, curriculum leadership, or textbook adoption, there are theological antecedents and influences that curriculum scholars have investigated. Additionally, the theological training and experiences of curriculum scholars influence their curriculum theorizing, as seen, for example, in John Dewey’s *A Common Faith*; William Pinar, William Reynolds, Patrick Slattery, and Peter Taubman’s *Understanding Curriculum*; Madeleine Grumet’s *Bitter Milk: Women and Teaching*; Phillip Phenix’s “Transcendence and the Curriculum”; James B. Macdonald’s “Theory, Practice, and the Hermeneutic Circle”; Dwayne Huebner’s *The Lure of the Transcendent*; Michael P. O’Malley’s “A Critical Pedagogy of Soul”; Kathleen Kesson’s “Critical Theory and Holistic Education”; James Henderson and Kathleen Kesson’s *Curriculum Wisdom: Educational Decisions in a Democratic Society*; Patrick Slattery’s *Curriculum Development in the Postmodern Era* and “Toward an Eschatological Curriculum Theory”; William E. Doll’s *A Post-Modern Perspective on Curriculum*; and C. A. Bowers’s *Education, Cultural Myths, and the Ecological Crisis: Toward Deep Changes and Educating for an Ecologically Sustainable Culture: Rethinking Moral Education, Creativity, Intelligence, and Other Modern Orthodoxies*.

A particularly strong influence of Latin American Liberation Theology and Black Liberation Theology—and the related work of theorists such as, for example, Paulo Freire, bell hooks, W. E. B. Du Bois, and Cornel West—can be seen in the work of critical curriculum scholars and

critical race theorists such as William Watkins, Beverly Cross, James Kirylo, Lisa Delpit, Peter McLaren, and Geneva Gay. Feminist theologies of scholars such as Rosemary Radford Ruether and Mary Daly inform the research of many gender theorists in curriculum studies. Process theology and cosmology is used in the research of ecologically focused curriculum scholars and environmental science educators such as, for example, Florence Krall Shepard, C. A. Chet Bowers, and David Orr. Eastern theologies and native spiritualities influence scholars such as Four Arrows Jacobs, Mei Wu Hoyt, Hongu Wang, and Christopher Reynolds in curriculum research in both the arts and sciences. Theologies of the human body influence some curriculum scholars, such as Ugena Whitlock, who work in the tradition of queer theory to investigate the complexity of identities and genders. The intersection of economics and theology is evident in the work of John B. Cobb Jr. and Herman E. Daly, titled *For the Common Good*, which proposes an approach to community and economy rooted in sacred texts and traditions. Curriculum scholars committed to equity, democracy, and social justice often embrace this economic theology. Existentialism in curriculum research uses the theology of Søren Kierkegaard and Simone de Beauvoir, particularly as their work relates to ethics. Catherine Lugg, among many others, has researched legal issues related to religion and education. These are examples of the strong tradition of using theology as a method for curriculum research or as a metaphor for understanding curriculum.

## THORNDIKE, EDWARD L.

---

Edward L. Thorndike (1874–1949), perhaps educational psychology's most significant formative force, helped transition the emerging field from a primarily conjectural, philosophical endeavor to an experimental, scientific enterprise. This resulting paradigm helped focus curriculum studies on rigorous research methodology often directed toward the empirical investigation of outcomes. This reorientation has had a significant impact on classroom practices as well. Thorndike's role in this evolution was largely inspired by his great confidence that sound experimentation would produce reliable and valid quantified data that could then help solve educational problems. Thorndike's methods and objectives are the crux of much contemporary educational research, and in his own time, Thorndike was guided by his pragmatic empiricism to develop principles of learning, societal roles and instructional practices for schools, and a rationale for curricular modification.

Through his research, Thorndike posited many principles of learning, including the law of effect. The law of effect states that if one's response to a stimulus is followed by satisfaction, then the response is more likely to reoccur in an identical situation. Likewise, responses followed by dissatisfaction are less likely to reoccur in identical situations. Therefore, one learns through rewards and punishments that strengthen and weaken connections between stimuli (S) and responses (R).

Originally, the Law of Effect was derived from Thorndike's work with animals, specifically chickens, dogs, and cats. The most famous experiments were conducted with cats that were trapped inside a crude wooden cage or *puzzle box* that had only one trapdoor exit and food positioned

immediately outside. To free themselves from captivity and famine, the felines needed to perform a particular behavior that would open the trapdoor (e.g., pulling a string lasso). Generally, when placed in the box (S/the stimulus), the cats would engage in a variety of behaviors (R/the responses). In this manner, the cats learned as connections between stimulus (S) and response (R) formed. Through repetition, these connections were intensified and habits resulted.

Ultimately, Thorndike's research led him to produce a theory of learning called *connectionism*. The foundation for behaviorism, connectionism stated that learning occurred when relationships between detected stimuli and performed responses formed neural connections. Those individuals who were genetically endowed with the ability to more easily form an abundance of these S-R connections could more readily learn and possessed great intellect. Thorndike felt that this fairly small gifted cohort was more rational, efficient, and moral than the rest of the population, and therefore it should be in positions of authority to ensure a more habitable, humane society.

Thorndike contended that schools could not make individuals significantly more intelligent, but instead should help make society more efficient and address individuals' idiosyncratic needs. To this end, schools should use cognitive tests, which Thorndike helped pioneer, to appropriately group students according to innate ability. This use of tracking would prepare society's future leaders and would help in designing curricula to meet the needs of schools' diverse learners.

Within schools, Thorndike believed that pupils should be taught using empirically based evidence. Such instruction involved teachers introducing stimuli, thus eliciting desirable student responses and building neural connections. Additionally, educational leaders would use empirical, quantified data to guide school policy and curriculum. Because of his strong research agenda, Thorndike provided much data to help steer such educational decisions, including curricular content considerations.

The early 20th-century's dominant curriculum-shaping force was formal discipline. According to this doctrine, studying rigorous subjects (e.g., ancient languages, math) helped exercise and improve the mind's general functioning. This improved cognitive capacity could then be transferred to novel

situations. Armed with experimental results, Thorndike cast significant doubt on formal discipline by arguing that the transference of cognitive abilities was not universal, but only occurred when two skills share similar elements. In other words, Thorndike felt that if students were to become skilled in English, then they should study English and not Latin. Aided by this data, many curricular reformers were able to gradually supplant the formal discipline curriculum with a more modern curriculum, which included a greater variety of electives and fewer traditional subjects such as government and French.

Although Thorndike's work greatly influenced curricular studies and educational psychology, his views on learning and intelligence have been criticized. Many have noted that much of Thorndike's research dealt with animals, which is not necessarily the same as human intellectual processes. A number of learning theories have been introduced challenging Thorndike's theory of habit formation.

Other critics of Thorndike have attacked his vision for schools. Generally, these opponents do not assault Thorndike's aspiration to employ schools as fashioners of a more compassionate, efficient society; instead, they have challenged the particular means he advocated for schools and teachers. Such challengers have claimed that teachers, acting more like technicians than educators, presided over unegalitarian practices. Specifically, differentiated grouping and education that is based on psychometrically determined intelligence and projected social roles have been charged with inequality of opportunity and potentially creating a static, even caste-like social order. Counterarguments have asserted that ability grouping is an effective educational practice that could allow many capable students to achieve upward social mobility through meritocracy.

## TRACKING

---

Different groups of students are often exposed to different curriculums. This entry concerns the process by which students are sorted into these groups, based on factors such as educators' judgments of those students' intellectual abilities, past achievement, or potential for future accomplishments. Once students are sorted, curriculum and instruction are differentiated between classrooms. Terms used to describe these sorting practices include *ability grouping*, *tracking*, *leveling*, *streaming*, and *homogeneous grouping*.

Some researchers and educators have drawn distinctions between the first two terms, usually labeling as *tracked* those systems that place students at a given level across subject areas and labeling as *ability grouped* those systems that group students class-by-class. But the day-to-day reality is virtually the same for most students in schools approximating either definition. In fact, similar patterns of enrollment and learning emerge in choice-based tracking systems.

A National Research Council report recently recommended all tracking be eliminated, recommending instead strategies that ensure appropriately challenging instruction for students of varying skill levels. This and other authoritative detracking recommendations arise out of tracking's long record as an obstacle to effective classroom instruction.

The historical emergence of tracking coincided with the immigration waves of the early 20th century. Tracking was grounded in racist, classist, and paternalistic beliefs about these immigrants and others. The practice was embraced as an efficient and scientific method to provide members of this newly heterogeneous student body with schooling appropriate to each group's academic capacity and

future station in life. Today, tracking's defenders are more apt to speak in terms of readiness, although efficiency arguments also remain common. In theory, the process of tracking children is supposed to facilitate learning by separating them into groups, so that they are taught alongside peers of similar ability and apart from those with higher or lower abilities. In practice, however, even those researchers who favor tracking as a theory generally acknowledge that it lacks consistency, effectiveness, and equity.

Implementation's tension with theory is evident, for instance, in the actual homogeneity of tracked classrooms. Students with an extraordinarily wide range of ability or achievement levels—as measured by standardized tests—are grouped together within any given class. This is because enrollment criteria include (whether formally or informally) not just test scores and prior school achievement but also student behavior, student or parent preference, completion of prerequisites, teacher judgment, and counselor guidance. The resulting classes tend to be stratified by race and class. Disproportionate placement of African American and Latino students in low-track classes, and the corresponding exclusion of these students from high-track classes, has been found to occur beyond any effect attributable to prior measured achievement.

Early judgments about the students' capacities persist throughout their school careers. Placements, once made, tend to take on a life of their own. Lower-tracked students are caught in a downward spiral. Their education fails to prepare them in knowledge and skills, and their transcripts reflect missing prerequisites for more advanced courses. Labels become fixed, internally for students themselves and externally for teachers, counselors, and other students. Students enrolled in low tracks tend to immediately fall behind their high-track counterparts, and the achievement gap increases over subsequent years. This lack of effectiveness partly results from the difficulties teachers face when trying to make low-track classes academically engaging and challenging.

Although past research has repeatedly documented the negative effects of tracked systems, very little has focused on the process and results of detracking. In recent years, this has begun to change, with books and articles describing the elements of successful detracking. Yet, despite some

early promising results from these studies, tracking remains the status quo, particularly as students move into the middle and high school grades.

## TRADITIONALIST PERSPECTIVE

---

The traditionalist perspective represents the foundational idea that dominated the curriculum field from the beginning of the 20th century until well after the middle of the century. This perspective is connected to traditional curriculum work that is focused on the schools, and particularly on curriculum development as an orientation narrower than curriculum studies, in the service of teachers, administrators, and school personnel. Through this perspective, the traditionalist designed and developed school curriculum in the narrow sense of the term that served practitioners in teaching the appropriate content and instilling particular skills in an uncontested way. The traditionalist perspective pertains to curriculum development in service of schools and not as a larger cultural phenomenon in which schools are but a part.

The traditionalist perspective is derived from William Pinar's work, which in the second half of the 1970s provided a comprehensive image of the traditional field. Most of the curriculum work was field based and conducted by curricularists, former school people, whose intellectual and subcultural ties tended to be with school practitioners. Likewise,

curriculum writing had schoolteachers in mind. Even those who were teaching curriculum at universities were former school people with extensive field experience and with microscopic views of curriculum focusing on organizational, administrative, and instructional concerns, excluding connections to the larger system within which the school is located.

From a traditionalist perspective, the reason of being of curriculum consisted the first organized and systematic effort to design and develop programs of study, which was supported by a particular rationale focusing exclusively on schools. A representative person of the era was Ralph Tyler whose rationale became very influential and was one to be followed for several decades. In *Basic Principles of Curriculum and Instruction*, originally developed as a course syllabus, Tyler elaborates on the principles and rationale for viewing, analyzing, and interpreting the curriculum and instructional program of an educational institution. Tyler's principles of developing curriculum included setting educational objectives, choosing and organizing activities to attain these objectives, and evaluating the outcomes based on the set objectives. What became known as Tyler's Rationale became the basic guide adopted by the majority of curricularists and practitioners for many years. It still is an influential document in designing and developing daily lesson plans by school practitioners.

The curriculum field's birth in the 1920s and the theory that supported it, which was represented by the Tyler Rationale model, are connected to the happenings of that period. The focus of curriculum on a bureaucratic model, which was characterized by ameliorative orientation, ahistorical posture, and adherence to behaviorism and to a technological rationality, was shaped by the emerging scientism and the scientific techniques from business and industry. The curriculum worker, characterized by a technician's mentality, accepted the curriculum structure as it was, and was dedicated to the improvement of schools by comparing resulting behaviors with original objectives.

The move from curriculum development to curriculum studies—that is, from the curriculum field as merely a facilitator of institutional and state policy or mandates to curriculum studies for understanding how we have come to be what we

are as a cultural phenomenon—was initiated by scholars and philosophers who challenged the bureaucratic-technocratic character of the curriculum. Work that was not field based can be viewed as a reaction to the status of the curriculum, leaning toward a more progressive orientation. More progressives in the field, such as Thomas Hopkins, argued for a child-centered curriculum. George Counts argued for a curriculum focused on socially relevant problems, and democratic values, and Horace Mann Bond analyzed education as reproductive of the political status quo. These progressive undertakings are well-documented in the book *Understanding Curriculum*. In this context, educators were called to shift their work habits from technicians who implement a set curriculum to teachers who challenge their assumptions about curriculum and consider the needs of children.

## TRADITIONAL SUBJECTS

---

Traditional subjects are by far the most common conceptualization of the school curriculum. Although most people feel confident in their understanding of what is meant by the phrase *school subjects*, history illustrates that what is considered “traditional” in one era may be viewed as outdated in another era. The ongoing social process through which subjects become “traditional” or “nontraditional” is highly complex. Political realities and philosophical positions that undergird educational decision making at all levels are key to shaping the ongoing debate. What subjects are

considered traditional vary greatly depending on whether the purpose of schools is viewed to be the reproduction of the existing culture or the creation of a new social order. Similarly, traditional subjects for the education of society’s elite would be different from subjects for the education of the average citizen. One example from U.S. educational history quickly illustrates that traditional high school subjects began to change in the 20th century with the introduction of universal secondary education. Latin had been a traditional high school subject and college entrance requirement for at least two centuries, but it had all but disappeared from the high school curriculum by the 1950s. This entry begins by presenting background information related to school subjects and the change process. Then, using examples from the United States, this entry shows how traditional subjects have changed over time.

### Traditional Subjects and Changing Culture

Changes in thinking about education and schooling within a society tend to reflect the changes within that society. Definitions of curriculum and the “canon” of traditional subjects serve as examples of two interrelated concepts that have changed in tandem during the past two centuries. Before the late 19th century, curriculum and subjects were synonymous. The curriculum was designed to transmit essential cultural knowledge to society’s elite. This curriculum consisted of the study of fundamental subjects and the “great” books that codified the knowledge in each subject. With the advent of education for the general population in the early 20th century, curriculum began to be described in terms of intention—what subject areas should be included for general education of the masses. By the 1940s, U.S. schools began to more accurately reflect the true diversity of the nation and curriculum began to be expressed in terms of actual experience in schools. In reality, this translated into a listing of subjects, often divided into tracks, these diverse students would be required to take. By the end of the 20th century, curriculum came to focus on educational outcomes—what a student learned in school. One product of this emphasis was the codification of subject area knowledge into standards and benchmarks for various grade-level bands.

Although reforms and innovations wax and wane, subjects tend to remain the common curriculum organizer over time. They are also the most recognizable curriculum structure to parents, students, and teachers. However, change does occur in which subjects are included in the curriculum and which subjects are considered traditional. In the United States, where education is essentially a local enterprise, traditional subjects have varied across a state, region, and the nation. The local community's vision for education shapes the schools' curriculum and what subjects are considered traditional. The school that is commissioned to transmit the current culture will likely identify different traditional subjects than will a school specially made to change the cultural status quo.

### Traditional Subjects in the Colonial Era

Dame schools and Latin grammar schools are representative examples of colonial American schools. Established by Massachusetts law in 1647, these were the first attempt at public education in the United States. Shaped by the zeal of the Protestant founders of the colony, the purpose of education was primarily religious and secondarily civic. The core subjects of the dame school were reading and writing. Reading was given priority because of the Protestant emphasis on each believer being able to read the Bible. The Latin grammar schools, modeled after their English cousins, sought to develop students' faculties through the study of mathematics, Latin, and Greek. All studies were situated within the Protestant faith as well. The choice of these as core subjects emerged from the Protestant focus on the importance of the Bible as the Word of God. Readers of Greek and Latin could not only read the great books of Greek and Roman civilizations, they could also study early versions and translations of the Bible. Thus, at the elementary level, reading and writing English were traditional, whereas Latin, Greek, and mathematics were the traditional subjects at the high school level during the colonial era.

### Postcolonial Changes

Education received relatively little attention in the years preceding and following the U.S. Revolution. By the 1820s, however, the common school

movement began creating what would eventually become the U.S. public school. The common schools were founded to provide instruction in the *common branches* of knowledge, an early label for traditional subjects. Yet, consensus did not exist about what those common branches were. All parties agreed on the inclusion of reading in elementary education, but not everyone could find agreement beyond that point. Some communities and educators advocated the inclusion of writing, grammar, and arithmetic. Still others believed the sciences and history should also be part of the elementary school curriculum. As a result, by the 1890s, multiple subjects had been added to the common school curriculum resulting in an overloaded, fragmented curriculum. During the 19th century, reading, writing, spelling, grammar, arithmetic, geography, and history emerged as traditional subjects in the elementary schools. Although natural sciences were taught in some schools, many educational theorists argued against their study by elementary-aged children.

By the beginning of the 19th century, the Latin grammar school was all but dead in the United States. Its demise can be traced to several factors, but primarily it failed because society no longer valued its curriculum. First private academies and later public high schools came into existence to meet two demands of the new U.S. society: preparation of most students for practical living and preparation of some students for college admission. In trying to meet both of these societal needs, the number of subjects offered by high schools expanded almost without restraint. Latin, Greek, and religion remained subjects within these schools but new "traditional" subjects began to emerge. Many high school subjects were upward extensions of the elementary subjects, but others were unique to the high school, such as algebra, geometry, logic, rhetoric, bookkeeping, astronomy, and surveying.

### Efforts at Systemic Change

Multiple factors led to a push for educational reforms in the 1890s. Controversy over the elementary and secondary school curricula was central to the discussions. Two committees established by the National Educational Association addressed

the issues of elementary and secondary school subjects directly. Their reports set expectations of schools for the next 25 years. The report of the Committee of Ten was issued in 1893. The committee delimited its vision for the secondary school curriculum to nine subjects, most of which the committee said children should start studying in elementary school. This official, new version of traditional subjects included (1) English, (2) Latin, (3) Greek, (4) other modern languages, (5) mathematics (6) geography, (7) history (with civics and political science), (8) physical and space science, and (9) natural science (biology and physiology).

The Committee of Fifteen issued its report in 1895. Reformers had hoped to shrink the overall elementary school program and decrease the amount of time students spent repeating instruction in language and arithmetic in order to make more time available for other studies such as algebra and laboratory-based science. Although the committee's report did reduce the elementary school from 10 years to 8, language and arithmetic continued to dominate the school day. Language-related classes—reading, spelling, grammar, and writing—were fragmented into separate subjects with no effort to integrate them. Subjects for the first 6 years of school included reading, writing, spelling, grammar, arithmetic, geography, natural science, history, physical culture, vocal music, and drawing. Almost all subjects, including science, were to be taught with a memorization-recitation approach. Additional subjects were suggested for Grades 7 and 8: Latin, algebra, U.S. history, U.S. government, and a manual training class. Though some had lobbied for major change in the school curriculum, the reports of these two committees simply reaffirmed the list of traditional subjects while adding new subjects to it.

### Educating the Masses

During the early years of the 20th century, enrollments in public schools, particularly at the high school level, grew astronomically. The influx of large numbers of the general population into formal education created a stress on the school system. The classical-oriented curriculum as perpetuated by the Committee of Ten was viewed as inadequate to meet the needs of the “new” high school student. Nor did critics think it met the

needs of a growing, industrialized nation. The Commission on the Reorganization of Secondary Education was charged with casting a vision for a new U.S. institution: the comprehensive high school. The commission purposefully phrased its most influential work—the *Cardinal Principles of Secondary Education*—in nonsubject matter terms. Referring broadly to the academic subjects in the principle that students should develop a command of fundamental processes, the commission went on to include health, home membership, citizenship, vocation, leisure, and ethics as key educational objectives. These principles helped shape the public high school into the 21st century. One of the most profound influences of the *Cardinal Principles* was the committee's endorsement of vocational and career education as a valid component of the high school curriculum.

Although some believed the traditional academic course was not useful to most high school students, many educators believed all students were not capable of completing the traditional academic curriculum. Various techniques emerged for organizing students into classes or small instructional groups based on their perceived ability or readiness for studying a subject area. Once placed into a lower group, it was virtually impossible for a student to catch up with other students in a more advanced group. This practice of tracking students was implemented informally in most elementary classrooms and formalized in most high schools into college preparatory and vocational tracks.

During the first half of the 20th century, the percentage of high school students enrolled in traditional academic courses tended to decline while enrollment in the vocational courses, such as typing, increased. Two notable exceptions to this pattern were biology and general science. Science educators created the field of high school biology by integrating what were previously separate life science subjects, such as physiology, botany, zoology, and anatomy. General science was an attempt to integrate content from all of the science disciplines but ended up being the study of the separate science branch—life, physical, earth, and space sciences—for a few weeks each. Biology, general science, and typing all emerged as new “traditional” subjects, valued and taken by most students in high school.

Despite the language of the *Cardinal Principles of Secondary Education*, subjects continued to define the shape of high school curriculum. Educational leaders with different viewpoints continued to issue statements emphasizing the academic subjects as essential studies for high school students. *General Education in a Free Society*, released by Harvard University in 1945, sounded a cry for a return to a more traditional academic curriculum that still would provide room for elective courses in an area of the student's interest. This plan called for three yearlong courses each in English, mathematics, and science and 2 years of study in social studies. These courses would account for half of a student's high school program with the other half to be selected from academic electives, vocational courses, or the arts.

One of the most comprehensive pictures of the U.S. school curriculum in the 20th century was presented by John Goodlad in *A Place Called School*. Goodlad's research team discovered that although the subjects taught in school looked similar across the nation, the actual educational experience of a child could vary widely depending on where he or she lived and went to school. Typical elementary school curricula were organized around core academic subjects—language arts, mathematics, social studies, and science—and included enrichment subjects—art, music, physical education, foreign languages, drama, and dance. Language arts and mathematics still dominated the elementary school day even as they had in the 1890s. Social studies, science, physical education, art, and music were each allocated between 6% and 12% of the instructional week while language arts occupied 34% of instructional time and mathematics 20%. Between schools, the amount of instructional time each day varied substantially, with some teachers reporting spending as much as 50% more time on instruction than their colleagues in other schools. At the junior and senior high school levels, the pattern was less skewed toward English. However, in the high schools, approximately 24% of the teachers taught vocational or business courses. This was indicative of the academic-vocational split that resulted from the schools' explicit tracking systems for college preparation or career preparation.

## Standardization of Traditional Subjects

As the 20th century drew to a close, curricular concerns and efforts shifted to attempts to ensure equitable outcomes for all students in the public schools. A major outcome of this trend was the codification of subject-area knowledge into standards and related benchmarks to describe student learning in different grade ranges. Beginning with the National Council of Teachers of Mathematics (NCTM), different national and international subject-area specialist organizations wrote and published "national" standards for the traditional academic subject areas: mathematics, English-language arts, science, and social studies. Other traditional school subject areas that had not been dominant also produced standards: physical education, the arts, and modern languages.

Consistent with an emphasis on student learning outcomes, the development of subject-area standards, and an accountability focus, most states developed subject-area examinations for the traditional academic subjects: English, mathematics, science, and social studies. These four academic subjects have remained the core cluster of traditional subject areas since the mid-20th century. Their position of privilege was ensured during the first decade of the 21st century by the No Child Left Behind legislation because these are the areas tested to determine if schools are making adequate yearly progress. Whether other subjects that have been considered traditional in the past will remain key components of the K–12 school curriculum remains to be seen—what is considered traditional is subject to change.

## TRANSFORMATIVE CURRICULUM LEADERSHIP

---

Transformative curriculum leadership is a collaborative problem-solving process initiated and sustained by dedicated, disciplined educators. The goal is to inspire and enact sophisticated curriculum judgments that advance democratic education through subject matter instruction. The collaboration has six interrelated components: (1) the facilitation of subject matter understanding integrated with democratic understanding; (2) the practice of a continuously informing reflective inquiry; (3) the enactment of systemic deliberation linking designing, planning, teaching, evaluating, and organizing decisions; (4) the building of learning communities; (5) the public advancement of this curriculum leadership; and (6) the engagement in personal journeys of understanding conceptualized as *currere* by William Pinar. Transformative curriculum leadership is one way that educators can actualize John Dewey's vision of education as the "supreme" art in societies with democratic ideals.

There is no precise protocol or sequence in practicing the six interrelated components. However, initial research indicates that this problem solving necessarily begins on a small scale. In most educational settings, transformative curriculum leadership must be enacted in work contexts dominated by instructional management systems focusing on students' standardized learning, and therefore, the disciplined professional learning that is necessary to enact transformative curriculum leadership may not be valued.

There are three overlapping *phases* in understanding transformative curriculum leadership. During the *emergent* phase, educators study all six components of transformative curriculum leadership in light of their own vocational calling. Educators move into the *engaged* phase as they undertake the disciplined artistry associated with

transformative curriculum leadership work. This artistry can be envisioned as three particular applications of curriculum "disciplinarity," which is a concept advanced by Pinar. The horizontal dimension refers to addressing present curriculum challenges. Educators engage in disciplined deliberations over the immediate, here-and-now problems of facilitating student understanding. Joseph Schwab's body of work exemplifies the horizontal discipline. The vertical dimension refers to addressing historical curriculum challenges. Educators practice disciplined inquiries into the relationships between educational experiences and the possibilities for facilitating a deepening understanding of democratic living in particular cultural contexts. John Dewey's body of work exemplifies the vertical discipline. The diagonal dimension refers to addressing existential curriculum challenges. Educators undertake disciplined journeys of understanding attuned to democratic ethical fidelity. Maxine Greene's body of work exemplifies the diagonal discipline. For purposes of brevity, these three interrelated dimensions of curriculum disciplinarity can be described as deliberative, inquiry, and journey artistries.

Finally, educators transition into the *generative* phase of understanding as they undertake particular transformative curriculum leadership projects. In effect, this phase is grounded in experiential learning acquired through active problem solving. Initial research on this phase indicates that educators begin to acquire a generative understanding as they initiate one or more of the components of transformative curriculum leadership.

Transformative curriculum leadership is a visionary form of collaborative problem solving that can be difficult to comprehend. Educators and other important curriculum stakeholders may lack the experiential referents to conceptualize and value this work. To address this problem, four exemplary products of transformative curriculum leadership work are currently being developed and will be featured on a future Web site.

The first product will be an illustration of a *disciplined professional learning community* (DPLC). If educators could actually observe a DPLC in operation, they would have a much better conception of the three artistries underlying transformative curriculum leadership practices. A model DPLC is currently being organized. Video

clips and narrative expressions of this DPLC are being created. The second product will be illustrations of *student learning projects*. From the point of view of the educational consumer, projects that are designed to facilitate students' subject matter/democratic understandings are the key component of transformative curriculum leadership. These projects provide tangible evidence of the quality and value of educators' collaborative problem solving. Video clips of student learning projects culminating in student performances of understanding are also being created.

The third product will be illustrations of university-based and school-based *leadership endorsement programs*. These programs are designed to facilitate educators' professional development through the emergent, engaged, and generative phases of transformative curriculum leadership work. The focus is on continuous study and experiential learning culminating in educators' performances of understanding. These performances provide tangible evidence that educators can now function as responsible transformative curriculum leaders. Video clips of educators demonstrating their understanding of all three phases are being created. Applications of these leadership endorsement programs for preservice teacher education are also being created. These applications set the stage for the continuing professional development that transformative curriculum leadership requires.

The fourth and final product will be specific applications of an *evaluation instrument*. Transformative curriculum leadership requires continuous self- and peer-evaluation. Educators need regular feedback on the quality of their deliberative, inquiry, and journey artistries. This continuous evaluation is important because educators can quickly fall back into standardized instructional problem solving because of current conditions and pressures in education. In effect, educators can easily lose sight of education as the most important form of human artistry in societies with democratic ideals. This evaluation instrument can also serve as a key public leadership tool, providing the general public with a new type of report card concerning the key indicators of quality educational work. Educators who practice the three dimensions of disciplined artistry are displaying a very high level of professional and public responsibility. In effect, transformative curriculum leadership

provides educators and all other curriculum stakeholders with a constructive alternative to standardized accountability implemented through instructional management systems. Specific applications of the necessary continuing evaluation are also being developed.

## TRANSGENER RESEARCH

---

The general term *transgender* is applied to a variety of individuals, behaviors, and groups involving tendencies that diverge from the normative gender role (man or woman) commonly, but not always, assigned at birth, as well as the role traditionally held by society. Transgender is the state of one's gender identity (i.e., self-identification as man, woman, or neither) not matching one's assigned sex (i.e., identification by others as male or female based on physical or genetic sex). The term *transgender* emerged in the 1960s, popularized in the 1970s to describe people who wanted to live cross-gender without sex reassignment surgery, and expanded in the 1980s as an umbrella term to unite all those whose gender identity did not mesh with their gender assigned at birth. Today, the term has taken on a political dimension as an alliance covering all those who have at some point not conformed to gender norms, and the term is also used to question the validity of those norms. Within the field of curriculum, the

term continues to evolve because of the term's widespread media usage and impact on equal rights and antidiscrimination legislation.

Gender identity and transgender identity are fundamentally different concepts to that of sexual orientation. The overall goal of gay, lesbian, bisexual, transgender, intersex, and queer (GLBTIQ) research in curriculum studies is to enable school personnel (i.e., teachers, administrators, staff, coaches, curriculum specialists, media specialists, counselors) and community partners (i.e., parents/guardians, other members of the community) to protect children who are struggling with their gender identity by teaching all children tolerance, understanding, and empathy. This entry defines many terms and classifications associated with gender identity and development and then discusses associated curriculum issues.

### Definitions and Classifications

A transgendered person often considers himself or herself as a male or female trapped in the body of the "opposite" gender. Sometimes they feel as if they are differently gendered, yet neither male nor female. Transgendered people may choose to express their gender through verbal self-representation, dress, and deportment alone. Or they might pursue drug therapies or gender reassignment surgery to become transsexual. *Transgender* refers to a range of gender-atypical sexual identities. The term describes a group of individuals who do not exactly fit into the stereotype of what it means to be male or female in a given society.

In the past, the terms *homosexual* and *heterosexual* were used for transgender people based on their birth sex. The literature now uses terms such as *attracted to men* (androsexual), *attracted to women* (gynosexual), *attracted to both* or *attracted to neither* to describe a person's sexual orientation without reference to their gender identity. *Transgender* does not imply any specific form of sexual orientation. Transgender people may identify as heterosexual, homosexual, bisexual, pansexual, polysexual, or asexual. A definition of transgender is in a constant flux but generally includes (a) of relating to or designating a person whose identity does not conform unambiguously to conventional notions of male or female gender roles, but combines or moves between these;

(b) people who were assigned a sex, usually at birth and based on their genitals, but who feel that this is a false or incomplete description of themselves; and (c) nonidentification with, or nonpresentation as, the sex (and assumed gender) one was assigned at birth.

A transgender person may have characteristics that are normally associated with a particular gender, identify elsewhere on the traditional gender continuum, or exist outside of it as "other," "agender," "intergender," or "third gender." Transgender people may also identify as bi-gender or along several places on either the traditional transgender continuum, or the more encompassing continuums that have been developed in response to the significantly more detailed studies done in recent years.

Transgendered persons can be classified as (a) gender-benders, (b) transvestites, (c) androgyne, and/or (d) transsexuals. Gender-benders may behave or dress in a way that is atypical to their assigned gender to make a political statement or express their difference from conventional, mainstream society. For example, cross-dressing and trying to pass as a member of the opposite sex sometimes emerges in childhood and is also called primary transsexism. Autogynephilic or secondary transsexism emerges as a desire to change gender at puberty or later in adulthood. Cross-dressers' motivation may or may not be based on dissatisfaction with being male or female, but instead is often to entertain others as drag queens or kings or at costume parties. Generally, the term *drag queen* covers men doing female drag, *drag king* covers women doing male drag, and *faux queen* covers women doing female drag. Cross-dressers may or may not be homosexual. *Drag* is applied to clothing and makeup worn on special occasions for performing or entertaining as a host, hostess, stage artist, or at an event. This is in contrast to those who cross-dress for other reasons or are otherwise transgender. Drag can be theatrical, comedic, or grotesque, and female-identified drag is considered a caricature of women by some feminists. Within the genre of drag are gender illusionists who do try to pass as another gender. Drag has been regarded as an area where transgender people can find more acceptance and financial support than in mainstream work environments.

*Transvestite* is used for individuals who cross-dress for purposes of sexual gratification. Researchers

draw a distinction between males who dress as females or females who dress as males for sexual arousal and those who cross-dress for drag shows or for fun. Transvestites who cross-dress for sexual gratification often do so in private and are usually married, heterosexual men. Transgender activists may or may not consider these individuals to be members of their community and these heterosexual males may or may not consider themselves within the category of “transgender.”

*Androgyne* refers to individuals who assume or possess characteristics of both genders to feel emotionally complete. Androgeny suggests an expression of freedom from gender stereotypes or a lack of concern about whether one is violating gender norms. An androgyne is a person who does not fit cleanly into the typical gender roles of his or her society. Androgynes may identify as beyond gender, between genders, moving across genders, entirely genderless, or any combination or all of these. Androgyne identities include pangender, bigender, ambigender, nongendered, agender, gender fluid, or intergender. Androgyny can be either physical or psychological; it does not depend on birth sex and is not limited to intersex people. Occasionally, people who do not define themselves as androgynes adapt their physical appearance to look androgynous. This outward androgyny has been used in fashion, and the milder forms of it (e.g., women wearing men’s pants or men wearing two earrings) are not seen as transgender behavior.

The word *transsexual*, unlike the word *transgender*, has a precise medical definition. Many transsexuals believe that to be a true transsexual, one needs to have a desire for surgery. In any case, *transsexual* is used for persons who may not be psychologically comfortable with their gender. Males may feel trapped in a female body and vice versa. Their gender identity, or the way they identify in a gendered sense, is at odds with the physical body into which they were born. Psychologically, they may feel alienated from their biological sexed self. Transsexuals often seek to change their bodies to match their sense of identity and to change their physical appearance to be more like the opposite sex. Transsexual individuals may seek treatments such as sex reassignment surgery to modify their genitals, hormonal treatment to change secondary sex characteristics, or electrolysis to remove hair. Transsexuals who are transitioning from one

gender to the other may be at various stages in their transformation and are referred to as pre- and post-operative. Current definitions of transgender include the following: *transman* refers to female-to-male (FtM or F2M) transgender people, and *transwoman* refers to male-to-female (MtF or M2F) transgender people. FtM is usually a masculine girl and MtF is usually a feminine boy, but this is not always the case. There is a school of thought that says terms such as FtM and MtF are subjugating language that reinforces the binary gender stereotype.

Usually by age 3, people have a sense of what their gender is. Their gender identity is probably a product of both biology and socialization. Occasionally individuals develop gender identities that do not match their biological sex in a conventional sense. Some are intersexed (formerly called hermaphroditic) at birth and were surgically assigned a sex because of ambiguous genitalia or other physical sexual characteristics. Intersexed refers to individuals who are born with mixed sexual characteristics, that is with some male and some female characteristics. The Intersex Society of North America (ISNA) defines *intersex* as individuals who were born with the anatomy not traditionally regarded as standard male or female. ISNA draws a distinction between transsexual and intersexed; the former involves transitioning from one sex to the other with hormone therapy or sex reassignment surgery; the latter is defined by the physical anatomy the person was born with. Some transsexual individuals may be born intersexed, others are born with normally developed male or female anatomy. The practice of sexual assignment by surgery during infancy and then to raise a child within gendered norms as whichever gender is chosen is controversial and considered by some researchers to be a violation of one’s body. These individuals suggest that the practice of surgery on intersexed infants be halted and that the intersexual can choose or not choose surgery once she or he has reached adulthood. The extent to which intersex people are transgender is debated because not all intersex people disagree with their gender assigned at birth.

The conservative view is that sex determines gender and that there is no practical difference between the two. In this view, genitalia or “birth sex” or chromosomes deeply and permanently determine one’s essential identity as a woman or

man; trying to violate this divide is impossible, unnatural, and unhealthy. It is often pointed out that chromosomes are immutable and that a male will always look like a male, not a female, even after sex reassignment surgery and hormones. Some supporters of this argument assert that although transpeople may claim to feel like a certain gender, only a biological female can genuinely feel what it is to occupy a woman's body, including having experiences such as childbirth. These arguments are examples of biological determinism, and they do not generally address people who are infertile or both intersex and transgendering or passing transsexuals (all of whom actually exist).

### Curriculum Issues

Because of the varied terms and meanings, school personnel need to understand the necessity of choosing terms with respect to their students' gender identities and preferences. There always have been and always will be individuals who do not fit the traditional and arbitrarily defined categories of male and female—genetically, anatomically, or in how they identify. Understanding how individuals identify and are gendered enables us to understand that differences are normal, natural, and nothing to be afraid of.

In addition, gender stereotypes define masculinity and femininity by certain rigid patterns of behavior and appearance. Social norms often insist that children behave in ways that fit these stereotypes. Research points to how school personnel and community partners need to be aware of how our stereotypes about what is masculine and what is feminine influence our reactions to our children, sometimes in hurtful ways. Research also shows that these stereotypes can seriously distort a child's social and emotional development. For example, rigid masculine stereotypes harm the development of young boys and are linked to male violence and anger in society. If children do not feel they fit in the stereotypes roles of their gender, especially when they are not accepted by their peers, school personnel, or their families, research shows they are at a high risk for depression, feelings of alienation and hopelessness, and in some cases, suicide. The feelings of these children of being different, of being an outsider, may arise from early onslaughts of disapproval for gender nonconformity.

Research also shows that discrimination in society toward children who do not look or behave the way we expect them to look and behave according to their gender can be even more extreme than antigay discrimination. Transgendered people often do not consider themselves homosexual, and people who identify as homosexual often do not consider transgendered people to be part of the gay and lesbian community. In any case, transgendered people are still poorly understood and experience as much or more stigma and marginalization in school than gays and lesbians do. Research in this area enables school personnel to understand that transgendered people have a range of experiences and identities that they exemplify. It suggests that as children they may be as much or more conflicted or confused than are children who will grow up to be gay or lesbian.

A curriculum that presents transgender and homosexuality as natural and good may be politically challenging to school personnel; however, it is important for children to understand the multitude ways in which individuals can and do identify in terms of sexual orientation. All children benefit from transgender research in curriculum studies because the effects of prejudice and the basis of the prejudice toward transgendered persons is similar to that gay people and other marginalized individuals experience in our culture. In other words, transgender research points to ways in which the same level of acceptance and affirmation we do for diversity in gender, race, ethnicity, faith, and social class should also be extended to sexual orientation.

The issues around psychological classifications and associated stigma of cross-dressers, transsexual men and women (and for that matter, gay and lesbian children who may be difficult to tell apart from transgender children early in life) are in flux and continually changing. In any case, although transgender issues are controversial in both public and scientific spheres, it is important for school personnel to communicate to students that transgendered people are healthy and normal. Trans-affirming people should interrupt overt and covert curricular materials that are "transphobic," or "transbashing," and consider them to be personal attacks based on hatred or fear.

some are part of homeless families and others are street kids who face physical harm, and in some nations, murder. Transient children also include victims of human trafficking, foster children, child laborers, migrant children, and children experiencing residential mobility because of coping moves or forced moves. At the more fortunate end of the transient spectrum are children who are on the move because of their parents' diplomatic, military, missionary, or business career moves. Migrant children, the most mobile population in the United States, include children of agricultural workers who are often needed to labor in the fields and the offspring of families that do seasonal gardening work, meatpacking, vegetable and fruit canning as well as racetrack work that rotates among varied sites. From a worldwide perspective, many transient children are immigrants, internally displaced populations, or refugees. Estimates of the number of children experiencing transience exceeds 12 million. Yet little has been done to meet their curricular needs in a substantive, meaningful manner.

An educational definition of transient children has been explained in some U.S. school districts as, simply, the percentage of students who are not enrolled for the entire previous school year. The U.S. General Accounting office has reported alarming data indicating that, by the end of 3rd grade, one of six children in the United States has attended three or more schools. This study also reported that during a 4-year period, many U.S. schools can see less than 50% of their students remaining in their schools for the entire year.

The growing number of transient children reflects worldwide political, social, and natural crises with some of the victims of these worldwide issues appearing at the doorsteps of U.S. schools. Residential mobility in the United States has also grown and reflects the current mortgage and affordable housing crises in the nation. An estimated 2 million U.S. children have recently joined the ranks of transience because of recent mortgage foreclosures their families have suffered and the lack of affordable rentals in an era of condominium expansion and gentrification of neighborhoods.

When transient children arrive in U.S. classrooms, they often have health, social, and emotional needs in addition to educational needs. They require, perhaps more than some others, a holistic

---

## TRANSIENT CHILDREN RESEARCH

---

A wide array of children is subsumed under the term *transient*, and their life circumstances beckon thoughtful consideration of curriculum studies that meet their significant needs. Often suffering from poverty, reflected in their ranks are urban, suburban, and rural children who are homeless;

and integrative view of a curriculum. Access to basic nutritional needs and health care has often been inaccessible or sporadic as families are on the move. Emotional issues such as anger over uncontrollable situations and broken peer and teacher relations can develop. Frequently, new language learner needs and sensitivity to cultural diversity are required no matter how short-lived a transient student's attendance may be. Self-esteem may be low for these children because of the stigma attached to the economic, mobility, and housing issues they face. The little educational research that has focused on transient children reveals achievement lags and gaps as well as high correlations between transience and dropout rates.

Few school districts develop meaningful curricula for transient children as current assessment foci and record maintenance and transmission become overwhelming concerns. Transient programs that are touted as models in the sparse extant research, such as the "Staying Put" project of the Chicago Public Schools, concentrate on heightened educational, communication, and newcomer activities that involve parents.

Educating transient children is inexorably intertwined with wider policy issues that affect the facilitation of a meaningful curriculum for these students. Two particularly important policy advances have affected educators' abilities to engage in curricular development with transient students. The McKinney-Vento Act recently reauthorized the right of homeless children to remain in one school while they are using emergency shelters and to enroll in school immediately even if they lack documents typically needed for enrollment or a legal guardian. The McKinney-Vento Act also requires a school to provide special education, gifted and talented programs, services for English language learners, vocational education, and school nutrition programs for homeless students. In addition, it requires every school district to designate a McKinney-Vento liaison to work with children experiencing homelessness. It also establishes a state level office for support, technical assistance, and monitoring.

A second nationwide policy advancement that has international aspects is the electronic interstate record transfer system of the federal Migrant Education Program. This program has also tried to develop a working relationship with schools in

Mexico in an attempt to ensure appropriate educational placement for migrant students. Record transfer is considered a key element for curriculum continuity and the fulfillment of graduation requirements. The federal Migrant Education Program has also initiated national distance-learning programs and a laptop computer program for secondary students. These technologies have given some students accessibility to curricular programs aimed at continuity in instruction and credit accumulation.

Curriculum designs for transient children need to attend to basic affective classroom practices such as creating an atmosphere or classroom culture that is accepting and sensitive to the diverse needs and backgrounds of these students. Strategies for working with linguistic diversity are particularly helpful for teachers' professional development. In the spirit of Paulo Freire, L. Thomas Hopkins, and James Beane, curricular innovations that go beyond basic programmatic concerns for transient children would benefit from curriculum integration. To date, school and governmental policies have dominated the curriculum for transient students in the United States; basic skills transmission has become their most typical fare. An expedient, measurable, tractable, prescribed curriculum is presently pursued and advocated for children on the move. Curriculum integration would afford transient students the opportunity to pursue a curriculum that is personally and socially relevant. Transient students could bring their own frames of reference into a shared democratic learning process. Basic skills can be integrated in a connective manner with engagement and persistence in such a curricular design rather than presented as isolated and fragmented learning. Literacy materials can incorporate children's and young adult books that reflect the transient experience of other children such as Francisco Jiménez's classic memoirs *The Circuit* and *Breaking Through*. Transient children deal with much fragmentation in their lives, their curricula should integrate connections, social issues (which decidedly already affect them), and optimism for what they can overcome and become in a democratic society.

## TRANSNATIONAL CURRICULUM INQUIRY

---

An online journal published by the International Association for the Advancement of Curriculum Studies (IAACS), *Transnational Curriculum Inquiry* represents a forum for scholarly dialogue about curriculum research from national, regional, and transnational perspectives. The journal supports the development of a global yet nonuniform field of curriculum studies. Oriented for an international readership, the first issue of the journal was released in 2004. Since that time, one to three issues have been released each year. A peer-reviewed journal that seeks to encourage transnational conversations in curriculum inquiry, *Transnational Curriculum Inquiry* continues to be guided by Neil Gough of La Trobe University, the founding editor. Other editors include Catherine Camden Pratt, Lyn Carter, Melanie Ruchel, and Julie White.

In the inaugural issue of *Transnational Curriculum Inquiry*, Gough described the mission of the journal to build transnational and transcultural solidarities in postcolonial curriculum inquiry and to do so in such a manner so that innovative forms of global inquiry do not merely replicate or assimilate local and national forms of curricular discourse and practice. Gough discussed the reconceptualization of curriculum studies to form new constituencies and coalitions: democratic, multicultural, and transnational citizenries. He proceeded to pose the question that remains as a central issue for the journal: How

can national democracies with diverse histories and different social contexts collaborate to prepare future labor for a *global* economy and prepare citizens for an *international* polity? Topics addressed in the journal include human rights; democratization; national, ethnic, and religious identities; issues of gender, racial, and social justice; the concerns of indigenous peoples; and poverty and social exclusion.

Sections of the journal include keynote addresses and presidential addresses from the World Curriculum Studies Conference, articles, commentaries and conversations, and book and media reviews. A sampling of published essays includes "A Vision for Transnational Curriculum Inquiry" by Noel Gough, "A Bridge Between Chinese and North American Curriculum Studies" by William F. Pinar, "What Can Schools Do? Knowledge, Social Identities and the Changing World" by Lyn Yates, "Curriculum Making on the Edge of Europe in the Age of Globalization: Two Alternative Scenarios" by Francisco Rodrigues Sousa, "Bildung and the Internationalization of Curriculum Studies" by William F. Pinar, "Curriculum Studies and Transnational Flows and Mobilities: Feminist Autobiographical Perspectives" by Janet L. Miller, and "Rendering Dimensions of a Liminal Currere" by Pauline Sameshima and Rita L. Irwin.

## TRANSNATIONAL RESEARCH

---

Curriculum research can take many forms including those that transcend national boundaries. Such research provides perspectives that are either cross-national (involving several national jurisdictions and including direct comparisons of those jurisdictions or providing regional perspectives across a group of countries) or international (involving multiple national jurisdictions that might be taken to give international coverage). Such research is often set in quite specific theoretical frameworks, but this is not a necessary criterion for designation as transnational. A broad range of possible theoretical possibilities encompasses such research, and these are discussed later to frame transnational curriculum research.

In an age of global interconnectedness that is often fueled by economic processes such as globalization, it might be expected that curriculum research across national borders will assume greater significance. Increased communication between researchers means that common issues and problems will be more easily identified and transnational research teams more easily formed. Nation-states themselves have readily recognized the value of international studies of student performance and researchers have picked up on the secondary analysis of these studies to provide more focused and at times more relevant research. Yet individual researchers have not been slow to recognize the value of national comparative research, especially those who have always worked within a comparative tradition where by definition comparison is the research method of choice. Transnational curriculum research, therefore, takes a variety of forms and relies on a range of methodologies. It can be used to address policy priorities that transcend national borders, it can pursue issues that affect individuals in different locations as they confront oppression and discrimination, or it can focus on traditional academic concerns that are common to different jurisdictions. The key point is that researchers are able to pursue such research collaboratively (i.e., in cross-national teams) and without constraints (i.e., without direct accountabilities to nation states). The benefits of such approaches will greatly enhance the field of curriculum studies.

## Theoretical Frames

The International Association for the Advancement of Curriculum Studies and its journal, *Transnational Curriculum Inquiry*, have made a concerted effort to create a theoretical framework for transnational curriculum research. The intention has been deliberately emancipatory in seeking to create spaces outside of the constraints of national boundaries to pursue curriculum research agendas. Working outside of national boundaries creates possibilities to think about curriculum issues and problems in new and different ways. The cross-fertilization of ideas that can occur in transnational spaces as educators talk and act can be a powerful force for change.

This theoretical framework is best understood in the broadest sense as postmodernist or post-structuralist. A reaction to the standardization and homogenization of curriculum thinking is often seen to characterize the modern nation-state. Neil Gough has referred to this theoretical stance as postcolonialist. This highlights that aspect of transnational curriculum research that is aligned to the achievement of social democratic goals and the creation of more just and tolerant societies. In this sense, transnational curriculum research is linked theoretically to broader movements in literary and cultural studies that have similar objectives that clearly locate academic work in the broader social, political, and economic contexts that construct them.

Yet, not all transnational curriculum research fits into a postcolonial theoretical framework. International organizations such as the Organization for Economic Development (OECD) and the International Association for the Evaluation of Educational Achievement (IEA) have been involved in the assessment of student learning across national boundaries for many years. Specific programs such as IEA's Trends in Mathematics and Science Study, the IEA Civic Education Study, and the Progress in Reading and Literacy Study, along with OECD's broad suite of assessment studies in its Program of International Student Assessment provide international comparisons of student learning. These programs are curriculum related in the sense that they are linked back to national curriculum requirements and standards. They are transnational in the sense that they include a broad range of countries

across the globe, and they provide a sense of student learning outcomes from an international perspective. They are also controversial because they often result in “league tables” of countries in which there are winners and losers. These programs are driven by common research questions and issues, involve the administration of common survey instruments, and are analyzed using advanced statistical techniques that provide a reliable basis for cross-country comparisons.

Theoretically, these international studies of student learning outcomes can be located in a positivistic research tradition that is underpinned by scientific techniques and assumptions, although this is not to claim that the studies themselves are necessarily scientific. This tradition does not exist independently from the social, political, and economic contexts in which it has developed over a long period. For the postcolonial theorists referred to earlier, however, the positivistic tradition is likely to be seen as a way of supporting those contexts rather than challenging them. Thus, the theoretical framework in which transnational curriculum research is conducted influences the rationale for undertaking the research, the research processes that are adopted and the use to which the research is put.

This brief review of postcolonial and positivistic approaches to transnational curriculum research does not exhaust the theoretical possibilities that both create and guide such research. Within the field of education, there has been a long record of research that can be labeled comparative in nature. The field of comparative education is not exclusively concerned with the curriculum, but studies of cross-national and international curriculum comparison have played an important role in the field. There is an eclectic use of research methods in comparative education, and both the postcolonialist and the positivist will be found. This is because comparison itself is seen to be a method of knowing or learning about phenomena, and there is no prescribed form the comparisons must take. They may be descriptive, analytical, or critical, and different researchers will bring different perspectives to the way they present comparative data and ideas so that learning can take place from the comparisons themselves.

The idea of comparative curriculum research across countries is as attractive to national

governments (for example, see *An International Comparative Study of School Curriculum* completed in 1999 by Japan’s National Institute for Educational Research and the 2003 study by John Cogan and his colleagues about the future of the school curriculum in the Asia Pacific region). This is because of the salience of comparison as a technique and way of knowing. National governments can ask why other jurisdictions do things that they do not, and researchers can probe for cultural, social, political, or economic explanations of phenomena that are observed on one location and not another. This process of comparison can also be problematic if not handled appropriately. What works in one context may be culturally constructed, and therefore simplistic attempts to transplant processes or structures from one cultural context or another would be inadvisable. This problem is often encountered by governments anxious to improve student learning outcomes by looking elsewhere for what seems to work best. Nevertheless, used wisely, comparison can be a powerful tool for understanding other cultures, other people, and other systems in an increasingly interdependent world.

### Benefits

There is much to be learned from the postcolonialist view that one benefit to be derived from transnational curriculum research is for the researcher. Interacting and negotiating with international colleagues about key issues, problems, and directions associated with such research has the effect of removing researchers from their comfort zones and enlisting them in a new world where their preconceptions, assumptions, and thought processes can be challenged. It can be enlightening for researchers to come to the realization that the worldview that has dominated their thinking for a long time is not shared by everyone else sitting around the table. This can equally be the case in national contexts as well. Yet in international context, it takes on a heightened importance because it is often reinforced by the search for a common language, a common set of means that can transcend national boundaries, and an inbuilt sensitivity to the feelings of other participants who clearly do not share the same worldview. Transnational research forces researchers to see the other and to

respond in meaningful and helpful ways to forge an alliance that can transcend the structures imposed by national mind-sets. Even the most liberal of curriculum researchers will be challenged by the need to seek common ground and platforms for future research efforts.

Yet the benefits of transnational curriculum research are not just for the researcher in the field of curriculum studies. Such research can also provide valuable new knowledge that can be applied to the school curriculum across countries. Suzanne Mellor reviewed the benefits derived from Australian students' participation in the IEA Civic Education Study in 2003. She argued that the single most important finding was the relationship found between opportunities students have for participation in their schools and their level of civic learning. This relationship was highlighted in the Australian data and across countries. The cross-country comparisons strengthened the finding for individual countries—it seemed to be a generalized finding. The relationship varied from country to country, and not all students benefited from such engagement. Yet, as governments and communities across the globe go about the process of seeking to improve civic literacy and civic engagement of young people, strengthening participation at the school level can be put on the national agenda of all countries. That is to say, the 28-country IEA Civic Education Study produced valuable new knowledge gained largely from the comparative perspective provided by such widespread involvement. This level of generalization is a benefit that is often not acknowledged but that is important if the results of international studies are to feed back into the local communities from which they originate.

There are also occasions on which the benefits derived from transnational curriculum research go beyond schools to the broader society. Jaap Dronkers and Peter Robert, for example, in their 2008 reanalysis of PISA data highlight the disparities in student achievement across modes of schooling within countries to show how private schools, whether independently or government financed, can benefit students. Apart from the fact that private schools benefit from attracting talented students, a key finding was that school climate really makes the difference in accounting for learning outcomes. This is a quite fundamental finding that

raises questions about the provision of schooling in social democratic countries. If it is that the extra resources available to private schools enable them to create more conducive environments in curriculum offerings and extracurricular activities, then students attending public schools are at a severe disadvantage through no fault of their own. Although this result is an important academic outcome, it also has significant equity implications for democratic societies and highlights the social function of the school curriculum in reproducing life chances for individuals. It does not solve the problem, but it does highlight it in a way that cannot be ignored.

Transnational curriculum research serves this social function in other ways as well. Within our individual national boundaries, especially in Western countries, issues of gender and ethnicity have been highlighted over the past decades. For example, gender gaps in the learning of school subjects such as mathematics and science have been highlighted, but generally in a way that has not stigmatized girls. Rather, what has come in for the most criticism has been the somewhat masculinized ways in which these schools' subjects have been constructed and taught over time. It is not that girls do "poorly" in mathematics and science (indeed, in most Western countries when girls take these subjects, they do better than boys), it is that these subjects in their pedagogical orientations have often not considered the ways in which girls learn best. Yet this Western construction of gender disparity takes on a new dimension in the context of transnational curriculum research that reveals in many countries girls will never have the opportunity to do mathematics and science and indeed may not even get the opportunity to go to school. This does not undervalue the importance of gender issues in the West, but it does put them into a broader perspective. Without this view that crosses national boundaries, Western researchers may believe that the "gender" issue, as it relates to the curriculum, has been solved or at least addressed when in fact on the transnational front, it is as deep and as inequitable as ever it has been.

There is, therefore, considerable value to be had from transnational curriculum research whether at the level of the individual researcher, in new knowledge for the field of curriculum studies, or in relation to broader social issues that can be

highlighted in transnational perspective. Just as globalization appears to render national boundaries irrelevant in terms of new financial and commercial processes as well as technological innovations, so too transnational curriculum research can look across borders to see how common problems and issues can be addressed. Such research itself can take advantage of new technologies and use them to achieve important social purposes rather than the economic purposes for which they were created. The use of technologies in new transnational curriculum research is an important area for future investigation.

Transnational curriculum research is not the only research that needs to be done in the field of curriculum studies because the nation-state is likely to remain the site for key curriculum decision making and deliberation. Yet, in a globally connected world working across boundaries, confronting common issues and problems together and seeking to maintain important social and democratic values provides an important agenda not just for individual researchers but also for the societies in which they live.

## TRANSRACIALIZATION

---

The term *transracialization* is often used to refer to acquiring (or appropriating) knowledge of race and racial identity, attributes, and behaviors of individuals or groups whose race is different from one's own. An individual might, for example, incorporate knowledge of racial characteristics based on exposure to a different racial group through family, or living immersed in a racially specific community. The process of taking on racial knowledge and characteristics is an act of crossing-over, changing, or melding physical and cultural differences ascribed to specific racial groups.

Transracialization includes a process of identifying and reconsidering one's position of power; particularly power linked to racial hierarchy, racial identity, and attitudes linked to racial identity experience. A component of the work in multicultural education promotes acceptance, understanding, and change in attitudes linked to one's racial or ethnic self. A part of changing one's views about race requires reconceptualization of one's identity in reference to another identity different from the self. The deeper understanding of one's race in reference to another provides an opportunity for the person to deepen understanding of his or her own racial identification.

### Importance to Curriculum Studies

Reconceptualists within the field of curriculum studies recognize the critical links among cultures, language, race, and sexual orientations, for example. Moreover, scholars believe that racial, ethnic, social class background, and sexual orientation are powerful identities shaping the classroom, teaching, and learning experience. Historically, curriculum designed for public education in the United States only included knowledge stemming from a predominately White experience and culture. With a noticeably and fast-growing non-White population in the United States, discussions linking race and education indicate grave implications for the preparation of future teachers who will ultimately have to teach in schools that are increasingly serving students from biracial and multiracial backgrounds.

Literature in education refers to the White experience and culture as mainstream culture. For

the curriculum and educational practices to be shaped by knowledge not otherwise accepted, curriculum developers must understand the ways in which the curriculum can address or include issues such as race in curricular design and pedagogical interaction. The curriculum content and process must cross over, fostering new understandings of how the social, political, and cultural contexts shape knowledge taught and what knowledge is ultimately learned. White preservice teachers may experience transracialization through informed discussions of race, ethnicity, and identities, and when they immerse themselves in communities and schools that are predominately families and students of color. The opposite can be true; students and educators of color may also experience transracialization through their own immersion in predominately White institutions or communities. In both situations, individuals observe and take in a more nuanced understanding of what it means to be White, or what it means to be a person of color in a variety of social and political contexts.

Transracialization is a call for blending, perhaps blurring of the almost solid boundaries of racial identities. Transracialization might be a concept that describes going beyond race, removing racial descriptors such as physical attributes, to focusing on behaviors, values, and attitudes that are shared by more than one racial group. Culturally relevant curriculum could be a transracial pedagogical practice (racial identities or knowledge of more than one group are considered in the pedagogical practice). A notion that cross-racial interactions can deepen an individual's understanding of people's experiences whose race is different from their own can be a central concern for educating teachers, for example.

Scholars of curriculum studies, education, and race/ethnicity studies have articulated theories about race identity development, understanding racial categorization, and defining race/ethnicity. For curriculum studies scholars, the connection most prevalent is the critical role that racial identification and experience play in the development of curriculum in schools and in the observation of curriculum (learned knowledge/experience) at play in the world around us.

## TRENDS IN INTERNATIONAL MATHEMATICS AND SCIENCE STUDY

---

The Trends in International Mathematics and Science Study (TIMSS) affects the field of curriculum studies by enabling a global conversation about mathematics and science curriculum, what is taught, and how it is taught. TIMSS is an ongoing study providing internationally comparable data on student mathematics and science achievement.

Knowledge of TIMSS is widespread among mathematics and science communities; however, fewer people are aware of the First International Mathematics Study (FIMS), First International Science Study (FISS), Second International Mathematics Study (SIMS), and Second International Science Study (SISS). In 1967, FIMS collected data on 13-year-olds and students in the final year of secondary school from 10 countries. Between 1966 and 1973, FISS collected data on 10-year-olds from 16 countries and on 14-year-olds and students in their final year of secondary school from 18 countries. From 1977 to 1981, SIMS collected data on a similar population as the FIMS across 20 countries. In 1983 and 1984, SISS collected data on a similar population as the FISS across 24 countries.

TIMSS data has been collected in 1995, 1999, 2003, and 2007 across 78 countries. In mathematics,

two companion studies accompanied the 1995 TIMSS involving Japan, Germany, and the United States. The first companion study's purpose was a detailed context for the mathematics results from the achievement study. Therefore, researchers developed ethnographic case studies in communities within the three countries. The second companion study's purpose was to capture mathematics instruction on videotape from classrooms involved in TIMSS. The first study emphasized that cultural context around learning mattered and simply because one country had higher test scores did not mean that another country should (or even could) adopt the other country's teaching practices. However, the second study did show that teaching styles between the United States and Japan vary widely. In 1999, a similar video study was conducted in science involving Australia, Czech Republic, Japan, Netherlands, and the United States.

TIMSS uses curriculum as its major organizing tool. Three curriculum components inform the TIMSS design: (1) the intended curriculum, (2) the implemented curriculum, and (3) the achieved (attained) curriculum. The intended curriculum is the mathematics and science curriculum that society believes students should learn. The implemented curriculum consists of what is actually taught, who is actually teaching it, and how it is actually being taught. The achieved curriculum is what the students have learned as well as their attitudes toward mathematics and science. Findings from SIMS showed that teachers did not always implement the intended curriculum. Therefore, TIMSS studied the intended curricula more deliberately.

TIMSS affected the field of curriculum studies by expanding the conversation about what is taught and how it is taught internationally. Overall results showed mathematic achievement in the United States was comparable with that of other countries at the 4th grade. At the 8th-grade level, the United States fell slightly behind, and in the final year of secondary school, the United States fell even further. An important curricular note is that by the close of secondary schools, internationally, curricula vary so broadly that an international comparison is more difficult. Another important component of the TIMSS is its inclusion of science curricula. As a curriculum currently marginalized in the United States because it is not tested, the

TIMSS reminds the world that science is foundational and should be a part of the international curricular conversation.

The TIMSS results showed that student mathematics and science achievement improves when curriculum goes deeper into a domain area. In U.S. science, students participate in engaging activities that are disconnected from science content. Similarly with mathematics, curriculum tends to address the many topics briefly rather than spending extended time on fewer topics. The results are students who are vaguely familiar with a wide variety of disconnected domains rather than students who have a deep understanding and mastery of an interwoven curriculum. TIMSS has brought that conversation of a more cohesive connected mathematics and science curriculum to the forefront.

## TYLER, RALPH W.

---

Ralph W. Tyler (1902–1994) was described in a 1977 issue of the *Phi Delta Kappan* as “Mr. Fix-it,” a moniker that is surprisingly insightful but also somewhat amusing as a way to depict the stoic statesman who many consider one of the defining

figures for the field of curriculum studies and one of the more important educators of the 20th century. But Tyler's work in the field of curriculum studies can be best understood as that of an individual whose career was based on assisting others to solve—to fix—their problems. From the 1920s and 1930s and his involvement in the Eight Year Study through the 1940s and 1950s and the publication of his renowned treatise, *Basic Principles of Curriculum and Instruction*, to the 1960s and 1970s and his role in helping establish the National Assessment of Educational Progress program, his career was based on helping others formulate solutions to complex situations. Tyler stated throughout his career that he never sought to develop a distinctive ideology or theory, yet his legacy in curriculum studies, as described and defined by others, includes a curriculum theory, the applauded and criticized Tyler Rationale, and a distinctive instructional practice, “teaching with behavioral objectives.”

No problem, as described by Tyler in *Research Methods and Teachers' Problems*, appeared too great or too insignificant for his attention, and all solutions seemed situational—a solution at one site might not be appropriate in another, a problem here could become an answer there. Tyler never embraced any approach that promulgated predefined curriculum programs or predetermined solutions. Although the Tyler Rationale was interpreted as a rigid, step-by-step procedure beginning with the formulating purposes (and identifying objectives, selecting, organizing, and evaluating experiences), classroom and school-related problems became the all-defining motif and starting point for the selection of purposes, outcomes, and objectives. This becomes crucial when one realizes that the Tyler Rationale was conceived not as a four-step process for curriculum development, at least as described by Tyler, but as a method to view, analyze, and interpret curriculum and instruction for those who were experiencing problems and concerns in the classroom.

Tyler began his professional career as a science teacher in North Dakota, taking degrees at Doane College and University of Nebraska. He spent one year in residence at the University of Chicago working with Charles Judd; however, his dissertation research was a component of W. W. Charters's *The Commonwealth Teacher Training Study*. Tyler

worked in bureaus of educational research first at the University of North Carolina, from 1927 to 1928, and then with Charters at Ohio State University beginning in 1929. In 1938, Robert Hutchins, president of the University of Chicago, hired Tyler to serve as the university's examiner and chair of the Department of Education, positions he held until 1948 when he was appointed dean of the Division of Social Sciences, serving until his retirement in 1953. In 1954, Tyler became the founding director of the Center for Advanced Study in the Behavioral Sciences, a position he held until his retirement in 1967 when he then focused exclusively on a 20-year career as lecturer and writer.

Although the Tyler Rationale helped to popularize curriculum development, his career may best be described as being within the fields of testing and evaluation. In this realm, the significance of Tyler's work, in relation to the field of curriculum studies, can be seen as conceiving an alternative to testing—what Tyler coined as assessment—and to his counterpart, Ben Wood, whose career helped define a standardized student testing movement and lay the foundation for the Educational Testing Service (ETS). During the 1930s, Tyler publicly criticized Wood and questioned the importance of measuring all outcomes of learning. For Tyler, student evaluation was to assist teachers in making curricular and instructional decisions. Evaluation was not merely constructing tests but involved the discussion of “e-valuating”—articulating and drawing out the *values* of schools and of teachers—leading ultimately to ontological and epistemological questions. Unlike Wood, Tyler recognized that evaluation influenced teaching and learning and believed that no test technician alone, without assistance from a subject-matter specialist, that is, a teacher, could construct a valid and reliable achievement test. Through their lifelong battle, deemed the Wood-Tyler Debate, Tyler in his own way may have protected the field of curriculum studies from what would have been an even more pronounced high-stakes testing movement that could have emerged decades earlier. It is somewhat ironic that the National Assessment of Educational Progress program, a project Tyler helped develop during the mid-1960s, would ultimately turn to ETS for the assessment instruments, an organization that arose from Wood's Cooperative Testing

Service, and would later be guided, misguided in Tyler's view, to a testing perspective partially defined by Wood. Although the history of curriculum has been described through the struggles of curriculum and foundation academics, an entirely different and revealing history of the field arises from examining the debate between Tyler's conception of curriculum and assessment and Wood's "test-technician" view of curriculum and testing.

The importance of a site-specific perspective greatly influenced Tyler's views of evaluation and assessment, terms that he maintained he introduced to the field of education, as he focused on the validity of a solution to solve problems rather on seeking to establish an accompanying degree of reliability. In a career-defining speech, "Evaluation: A Challenge and an Opportunity to Progressive Education," presented at the 1934 Educational Conference on Testing, Tyler underscored an emphasis on "validity" as educators sought to find solutions to problems. This was a significant departure from educational bureau researchers who examined the outcomes of curriculum as determined by validity and reliability. Tyler, whose sole interest was to assist teachers in finding solutions to specific problems, did not focus on the importance of reliability. Neither did he dismiss scientific inquiry and the traditional scientific model; rather, he highlighted the importance of school experimentation not to prove or predict outcomes but, more importantly, to suggest promising directions and possibilities for schooling practice. From this perspective, the Tyler Rationale offers guidance without necessarily creating some of the curricular limitations for which it has later been criticized.

To note certain misimpressions of Tyler's career and "canon": his middle name, Winfred, is often misspelled as "Winifred." Tyler is also commonly described as the director of the Eight Year Study and, implicitly, in charge of that project's Follow-up Study, the comparison of 1,425 pairs of students. In fact, Tyler was research director of the Evaluation Staff of the Commission on the Relation of School and College. He worked closely with the staffs of other participating commissions and committees; however, his primary role was in assisting with the development of a massive group of student assessment forms used by the secondary classroom teachers. Although he was involved with the initial

work of the "College Follow-up Staff," he was quite removed from the work of the Follow-up Study (and displayed some disinterest in that component of the Eight Year Study through the remainder of his career). Interestingly, Tyler never viewed himself as a "curriculum person," and, though often designated as a defining figure for the field, he never served as president of the American Association of Supervision and Curriculum Development or as vice-president of American Educational Research Association's Division B, Curriculum Studies.

Perhaps one of the greatest misattributions is the common assertion that Ralph Tyler is the father of the behavioral objectives movement in education. Tyler's call to "formulate objectives" required educators to reconsider their most fundamental educational goals and, when situated within the context of a situational problem, became a way to reestablish "intentions" (which perhaps would have been a better term to have used). Objectives did not represent the confining, convergent dimension that was later popularized in the 1960s and 1970s with behavioral objectives and management by objectives programs. For Tyler, behaviors meant all types of human reactions at all levels of cognition. In Tyler's work with the Eight Year Study, objectives were developed for nonobservable behaviors—social sensitivity, appreciation, personal and social adjustment—and never limited to overt behavior. In fact, human capabilities became Tyler's phrase of choice when discussing behavior, and he disagreed with the unfortunate outcomes of behavioral objectives when education was reduced to mere training. Two separate 1973 interviews—"The Father of Behavioral Objectives Criticizes Them" and "Ralph Tyler Discusses Behavioral Objectives"—make this point and many others, including his belief that behavioral objectives had become too specific.

The 1971 essay, "The Tyler Rationale: A Reappraisal" by Herbert Kliebard, has proven the most significant critique of Tyler's curriculum work. Although no satisfactory response has ever been prepared to address Kliebard's criticisms, Tyler attended conferences during the 1970s and 1980s and willingly engaged in discussions with those who questioned his curricular beliefs. Understanding Tyler remains as challenging as those many problems he sought to solve. Tyler, a

self-proclaimed progressive educator, represents a complex mix of radical and conservative ideas. When Tyler turned his attention to classroom problems, he persuaded educators to reexamine basic, taken-for-granted educational practices and traditions. When he urged the use of objectives, he was offering teachers the opportunity to reconsider their educational lives in classrooms, a setting deeply entrenched in 19th-century educational practices. And when he advised educators to attach behaviors to outcomes, he was placing the responsibility of evaluation in the hands of teachers and encouraging them to look critically at the consequences of their actions. In many respects, his work continues to justify those activities for educators of the 21st century even while his rationale is currently scorned and criticized by many in the field of curriculum studies.

Yet, with the many accolades, Tyler also worked within the safety of the status quo, within an accepted educational system and already-established mores. In this role as facilitator, others—not Tyler—determined educational practice and made decisions for which they were held responsible. Tyler never took full responsibility for the misuse of the Tyler Rationale. In what is certainly an odd statement from one of the most important educators of the 20th century, he once stated that one cannot take responsibility for the actions of others and, seemingly referring to the Tyler Rationale, to establish new terms when a concept becomes a cliché. Martin Dworkin once stated that John Dewey was a figure of partisan fiction. In retrospect, the same can now be said of Ralph Tyler.

## TYLER RATIONALE, THE

---

The Tyler Rationale consists of four fundamental questions that first appeared during the late 1940s in Ralph W. Tyler's curriculum syllabus, *Basic Principles of Curriculum and Instruction*. This document is still in print and continues to sell thousands of copies each year. The questions of the Tyler Rationale include these: What educational purposes should the school seek to attain? What educational experiences can be provided that are likely to attain these purposes? How can these educational experiences be effectively organized? How can we determine whether these purposes are being attained? These questions rest on a conceptual foundation where educational purposes are defined by objectives that arise from three sources—the needs of the learner, expectations of society, and insights from content specialists. Because a program's educational objectives may become too divergent and numerous, the rationale was to filter objectives through philosophical and psychological screens. This simple array of four questions has proven to be one of the most defining professional concepts of curriculum design and development.

Much lore surrounds the origins of the rationale. Tyler, as research director of the Eight Year Study, describes a lunch occasion in the 1930s when he, H. H. Giles, and Hilda Taba were discussing curriculum development and the rationale's legendary questions were conceived (by Tyler) and written on a napkin. During the same period, Giles and the Eight Year Study Curriculum Associates were charged with formulating basic principles for the secondary school curriculum and, on the first page of their 1942 report entitled *Exploring the Curriculum*, their fundamental questions included these: What is to be done? What

subject matter is to be used? What classroom procedures and school organization are to be followed? How are the results of the program to be appraised? Both frameworks stressed the use of educational objectives, although neither represents the use of behavioral objectives as the term was later developed.

Tyler's call to "formulate objectives" required educators to reconsider their most fundamental educational goals and, when situated within the context of a classroom problem, became a way to reestablish "intentions" (which would have been a better term to have used). Objectives did not represent the confining, convergent dimension that was later popularized in the 1960s and 1970s with behavioral objectives and management by objectives programs. In fact, Tyler, Giles, and the Curriculum Associates describe the genesis of educational objectives in relation to the central purposes of education. For Tyler, behaviors meant all types of human reactions at all levels of cognition, and objectives were developed for nonobservable behaviors: social sensitivity, appreciation, personal and social adjustment. Yet, the Tyler Rationale is now often cited to have introduced behavioral objectives, even though Tyler later dismissed this claim and maintained his belief that behavioral objectives had become too specific. Further, the four questions were not meant to be a linear sequence of actions but, instead, questions as aspects of a conversation. Further, "why" questions were not part of the rationale, in part, because Tyler originally used the framework to assist teachers with immediate (classroom) problems. That issues of "purposefulness"—the why of a situation—would be implicitly addressed when one sought to identify (what) and to solve (how) problems.

Tyler was described by Robert M. W. Travers as having a genius for formulating plausible and simple solutions to complex problems. The Tyler Rationale exemplified this practice of clarifying procedures and stating ideas in uncomplicated ways and, when placed in the context of 1950s school district consolidations and the emergence of the curriculum specialist, Tyler's Rationale offered

a simple framework for educational administrators to design and develop curriculum, and to define the field of curriculum design and development.

Tyler altered the rationale during his career. At the 1960 Milwaukee Curriculum Research Conference, organized by James Macdonald, Tyler introduced a much more normative base to the rationale by restating the first question as "What are the proper objectives of the school?" At the 1976 Milwaukee Curriculum Theory Conference, organized by Alex Molnar and John Zahorik, Tyler identified two areas that he believed deserved greater attention: emphasizing the learner's active role in the educational process and examining the nonschool areas of student learning. Often viewed as a direct, value-free curriculum development process, the Tyler Rationale has received great criticism for embodying questionable values. Perhaps the most significant and critical assessment was published by Herbert Kliebard in the 1971 essay, "The Tyler Rationale: A Reappraisal." Kliebard questioned the historical accuracy of the foundations of the rationale and the conceptual soundness of the sources of objectives and the use of the philosophical and psychological screens. No satisfactory response has ever been prepared to address Kliebard's criticisms. The Tyler Rationale seems to have become a curricular shibboleth separating those who embrace and those who oppose a 20th-century tradition of curriculum development.

## UNIT TEACHING

---

Units are often considered the building blocks of successful instruction. When a teacher is assigned a particular subject or course to teach, one of the first tasks he or she approaches is the breaking up of the course into a series of units of instruction. The reasons for this approach vary, but although students, and often their teachers, find it difficult to conceptualize an entire course ranging across a 10-month span of time, it is also difficult to assist students in the creation of meaning using only daily lesson plans. Unit teaching provides a structure whereby teachers can work with students to achieve learning goals while creating meaning by providing a larger, less fragmented approach to instruction, a goal congruent with both Gestalt psychology and information-processing learning theory. Unit planning is historically credited to Johann F. Herbart and Henry C. Morrison with a variety of curriculum specialists recommending adaptations, for example, William Kilpatrick's project method. A teaching unit is generally conceived as a 2- to 6-week block of instruction depending on the topic and the developmental stages of the students.

Units are generally divided into two major categories: resource units and teaching units. Most "methods of instruction" textbooks, regardless of subject or grade level, recognize this division. The *resource unit* is an all-encompassing, general approach that enables teachers to select and modify materials for a specific instructional group

(class). As such, there is more material in a resource unit than any individual teacher would be able to use when teaching the unit topic. The *teaching unit* is an instructional block that is targeted at a specific group of students. Teachers frequently adapt resource units, designed either commercially or collaboratively, into teaching units for their individual classrooms.

Regardless of the category, units usually include the following components: title/topic; rationale or justification for study; unit goals (general) and objectives (specific) in cognitive (knowledge), affective (values), and skills domains; daily lesson plans aligned with unit goals and objectives including a variety of instructional strategies (differentiated activities to meet the needs of all learners); a list of materials and resources needed for unit completion; and, an assessment plan to ensure that goals and objectives have been learned. Recently, Grant Wiggins and Jay McTighe have advocated "backward design" by moving the assessment plan to the forefront of the unit and lesson plan, immediately following listed goals and objectives. This is to encourage teachers to consider the curricular alignment aspects of unit and lesson planning rather than viewing units simply as a collection of activities around a common topic. Evaluation consists of both formative and summative assessment regardless of design technique.

Units may be classified by their approach to teaching the material. Subject matter units can be single subject or fused, for example, a language arts unit rather than separate spelling, literature, and writing units. Units may be further integrated

in either a multidisciplinary or an interdisciplinary manner. This means that units can be correlated among teachers so that students either are studying the same chronological period in both language arts and social studies or the same conceptual theme or topic, such as space, in multiple subjects. That would mean that all students would spend time studying units on the concept of space as used in multiple subjects such as science, math, English, and social studies but these units would not necessarily relate to one another. These multidisciplinary approaches are not the same as a truly interdisciplinary unit such as a project or a problem-solving approach where students would be called on to integrate any subjects necessary to solve the problem or complete the project under study. This approach can be used either within a subject area—for example, social studies or general science—or across subject areas. These latter units are significantly more student centered in their approach than are more traditional units.

Some teachers might believe that in this current period of standards-based instruction unit teaching is no longer necessary. Nothing could be further from the truth. Well-planned units, focused around essential questions and important concepts motivate students while bringing meaning and context into the information being mastered. The potential for collaboration on resource units that can be transformed into teaching units, especially across disciplines, points the way for teachers to break down the walls of isolation created in individual classrooms and assist teachers by creating more holistic approaches to learning.

## UNIVERSITY OF ALBERTA COLLECTIVE OF CURRICULUM PROFESSORS

---

The University of Alberta's College of Education established itself as a center for the expansion of phenomenological, hermeneutic, and narrative inquiry in curriculum studies through the innovative scholarship of Ted Aoki and a cadre of students and colleagues including Max van Manen, Terrence Carson, David Smith, and the work of the Center for Research for Teacher Education and Development directed by D. Jean Clandinin.

Aoki moved from the social studies classroom where he had distinguished himself as an exemplary teacher to the faculty of the University of Alberta in 1964 at the invitation of Lawrence Downey, chair of the Secondary Education Department. When he retired some two decades later, having assumed the chair of the department, Aoki had earned a reputation as a dynamic public speaker and mentor but was not widely published. In his retirement, Aoki expanded his influence through the printed word, exploring the tension created in the life of the teacher between the curriculum plan and the "lived curriculum." Aoki evoked insights of phenomenology and postmodern philosophy to challenge the limitations of traditional curriculum studies that focus on development and implementation and reversed the curriculum act to see how it lives in the classroom. Aoki sought to understand what it means to be a teacher with a public responsibility to address the planned curriculum and the real relationship with students that constitutes the enacted curriculum. As he worked to more carefully speak and write to this tension, phenomenology informed both the inquiry process and the genre of expression. The works of Martin Heidegger and M. Merleau-Ponty provided a lens for this inquiry; Aoki later used insights from Jacques Lacan and Emmanuel Levinas in exploring the teacher–student relationship.

When van Manen joined Aoki at Alberta, first as a student from the Netherlands, receiving his doctorate in 1973, and then as a colleague, he brought phenomenological inquiry into schooling as articulated by Martinus J. Langeveld and the Utrecht School. Van Manen envisioned the

expansion of phenomenology inquiry into the various dimensions of the adult-child relationship, producing his own studies on the teacher-student relationship and exploring his method in *The Tact of Teaching*. In this work, van Manen moved with careful, insightful awareness to make the assertion that “tact” is an essential quality in meaningful teaching. Van Manen has been consistent in his promotion of phenomenological inquiry, founding the journal *Phenomenology and Pedagogy* to create a forum for the promotion of this inquiry into the lived curriculum.

D. Jean Clandinin, expanding on teacher narrative initiated while at the Ontario Institute for the Study of Education, serves as director of the Center for Research on Teacher Education and Development at the University of Alberta. Clandinin directs doctoral students in ongoing inquiry into teacher knowledge and teachers’ professional knowledge landscapes, consistent with the inquiry method she and Michael Connelly advanced for two decades, examining practical opportunities to make use of the method in improving the education and craft of teachers. Clandinin also encouraged the application of narrative inquiry for research in different professional fields, particularly in health services with emphasis on awakening the ethical issues that are contextual in professional encounter.

Evocative writing, characteristic of the phenomenological approach to understanding curriculum, to a hermeneutic cycle that uses insight to guide action and further inquiry was also developed by other faculty members at Alberta. Terry Carson has promoted the extension of phenomenological hermeneutic inquiry to teacher action research, using the hermeneutic conversation to understand and effect change. David Smith explores hermeneutic study to consider ethics in a world community, economic globalization, and education’s service to promotion of cross-national and cross-cultural marketing. Jan Jagodzonski examines postmodernism and how it transforms art education, including the interplay of psychoanalysis, feminism, linguistics, and fantasy with the expanding forms of aesthetic expression through imaginative uses of traditional and electronic media.

## UNIVERSITY OF CALIFORNIA, LOS ANGELES, COLLECTIVE OF CURRICULUM PROFESSORS

---

The University of California, Los Angeles (UCLA), was a significant center for curriculum study, focusing primarily on school curricula and reform, beginning in the 1960s with the contributions of John I. Goodlad and Louise L. Tyler, joined by John D. McNeil in the 1970s, and Jeannie Oakes in the 1980s. The contributions of Madeline Hunter to instructional planning and W. James Popham and Eva Baker on assessment were widely adopted in school practice and entered into discussion on curriculum planning. The focus on curriculum as a force for social change has been retained at UCLA in the writings of Peter McLaren.

For three decades before her retirement in 1988, Tyler was a demanding presence at the UCLA department of education, later the Graduate School of Education and Information Studies. Tyler came to UCLA in 1959 from the University of Chicago where she studied with (and married) Ralph Tyler. Louise Tyler’s enduring interest was in bringing the insights of psychoanalysis into curriculum scholarship, but in the late 1960s, she joined the dominant discussion on the value of educational objectives. Critical of Roger Mager’s restricted definition of behavioral objectives, Tyler was positively disposed to a broader approach taken by her colleague at UCLA, Popham.

Goodlad studied with Virgil Herrick and Ralph Tyler at the University of Chicago, earning his doctorate in 1949. Goodlad came to UCLA in 1960 following publication of his proposal with Robert Anderson that chronological age not be the basis of student grouping, garnering national attention and reaction. As director of the laboratory school at UCLA and then as dean of the UCLA Graduate School of Education, Goodlad was a leading advocate of team teaching and multi-age grouping. In his first decade at UCLA, Goodlad (with Maurice Richter) devised a conceptual system for dealing with curricular and instructional problems, and in *School, Curriculum, and the Individual*, suggested the four key questions that constitute the Tyler Rationale be considered in each of three forums where curriculum and instruction are developed: society (legal and policy deliberation), institution (district and school deliberations), and instruction (teachers and groups of teachers focusing on identified groups of learners). He urged recognition that curriculum development is inevitably value-bearing and must be deliberated on rationally to discern these values (a concern maintained throughout his career). In the 1970s, Goodlad translated his study of the practice of curriculum development to a conceptual design with three major elements. *Substantive deliberation* is the central intellectual discussion to determine curriculum, instructional methods, and assessment. *Political-social elements* in development are stakeholders who contribute to the process; *technical-professional elements* set the process into a formal process for translating deliberation to school practice.

The Study of Schooling bridged Goodlad's consideration of curriculum development theory over to school practice and resulted in a major statement in 1984 as *A Place Called School*. Goodlad's research group confirmed that the majority of time spent in schools was dominated by teachers talking or students completing institutional procedures. A reform curriculum was suggested consisting of language arts, mathematics and science (up to 36%), with social studies, the fine and practical arts (up to 30%), and physical education (up to 10%) completing the curriculum base with a common studies core to establish disciplinary connections. The balance of time was dedicated to electives for student interests.

Another major finding coming out of the Study of Schooling was how ability grouping or "tracking" influenced teacher expectations on student performance as well as student self-perception and achievement, particularly students identified as low in academic aptitude. Goodlad recommended eliminating tracking. A contributor to the Study of Schooling, Oakes's work on the effects of ability grouping, *Keeping Track*, was a timely contributor to curriculum and instructional practice in the era of *A Nation at Risk*. M. Frances Klein was a major contributor to Study of Schooling and used this data to expand the call for reform in elementary education arguing for the establishment of a constructivist curriculum that is responsive to the local curriculum.

McNeil produced an original synoptic curriculum text in 1977 that went through numerous editions. Organizing curriculum thought in four orientations (humanist, social reconstructionist, technology, and academic subjects), McNeil explored dimensions of curriculum development particularly relevant to administrators: learning opportunities, management, implementation, and evaluation as well as politics, theory, and research.

## UNIVERSITY OF CHICAGO COLLECTIVE OF CURRICULUM PROFESSORS

---

The department of education at the University of Chicago has been the intellectual home for a variety of influential voices in curriculum studies, historically ranging from the work of John Dewey

at the University Laboratory School through to the scholarship of Phillip Jackson in the 1990s and theoretically ranging from the science of education of Charles Judd to the human relations approach of Herbert Thelen. In addition, the University of Chicago was the base for classical liberal arts proposals of Robert Maynard Hutchins, Mortimer Adler, and the sharp criticisms of higher education and popular culture by Allan Bloom.

Dewey's tenure at the University of Chicago was relatively brief (1896–1904), and he served as professor of philosophy while founding the Laboratory School where he developed and evaluated his ideas on child development and activity learning. Dewey was a frequent visitor to Hull House and gathered further insight into the dynamics of experiential education from the programs offered by Jane Addams. Relative to application to the public schools, Dewey served as mentor and colleague to Ella Flagg Young, the first woman to assume superintendence of a large urban school system. Drawing on these experiences, Dewey produced works (*The Child and the Curriculum* and *The School and Society*) that proved to be among his most accessible and are significant early contributions to curriculum thought. Colonel Francis Parker, widely known for his advocacy of group and activity-based education centered on engaging the interests of children, accepted an offer to establish a teacher training institute and elementary demonstration school on the University of Chicago campus. The Chicago Institute was established at the University of Chicago and became the basis of the Department of Education at the university. In 1902, the Chicago Institute and the Laboratory School merged.

With the departure of Parker and then Dewey in 1904, the Department of Education took on a new identity, largely dominated by the vision of Charles H. Judd. Trained in Wilhelm Wundt's school of experimental psychology at the University of Leipzig, Judd was convinced that scientific study could advance the scholarship status of education as it was doing for psychology. Judd preferred to engage in field studies and educational experiments to measure the effectiveness of instruction as represented in his work, *Measuring the Work of the Public Schools* in 1916. Under Judd, the University of Chicago attracted students who furthered the scientific study of the public schools, educational

policy-making bodies, and other universities. The early works of Harold Rugg and George Counts, for example, both working under Judd, evidence this focus on empirical investigation.

The effort to establish a "science" of curriculum development was evident in the activity analysis proposal of Franklin Bobbitt. Influenced by social efficiency experts such as Frederick Taylor in industry, Bobbitt suggested school instruction should emulate tasks performed by capable adults in society. Skills, particularly those most frequently needed in productive and efficient living, were analyzed to their specific elements, then carefully cataloged and translated into learning experiences for students in schools. Assumed in this model was the skill base that would make for a productive life. Bobbitt's 1918 statement, *The Curriculum*, is a contender as the first major modern book on curriculum. In 1924, Bobbitt produced a practical recipe for activity analysis curriculum building in *How to Make a Curriculum*. Bobbitt's prescription for curriculum development was widely regarded as "scientific," given it was based on empirical observation of activities ordered into specific behaviors. The basis of this model, however, was the imitation of existing skills rather than the development of new knowledge and skills for a future society.

Although W. W. Charters's later association with Ohio State University eclipsed his tenure at the University of Chicago, as a colleague of Bobbitt, Charters developed his variation of activity analysis in 1923 with *Curriculum Construction*. Charters contended the starting point for curriculum construction should not be analysis of existing practice but, rather, in direct application of social efficiency experts, the idealized description of what a skill should be to be most productive and efficient. Charters's inclusion of social ideals introduced social analysis and evaluation that was implied but not emphasized in Bobbitt's model.

Henry Morrison, also colleague of Bobbitt at Chicago, was decidedly opposed to the proposal that scientific inquiry resolved humanity's search for meaning. Working from a natural law perspective, Morrison maintained that science provides answers irrelevant to the questions that philosophy asks; scientists must respect philosophy for harmony in human thought. In the resulting curriculum, the individual personality is refined by the

principled habits of a civilized life. The academic disciplines were the most appropriate forum for presenting civilization in that they reflect the elements of the human personality. The major sciences of history, geography, physics, chemistry, biology, human physiology, hygiene, civics, economics, and elementary jurisprudence contributed to forming the intelligent person.

In his work for secondary school education, Morrison recommends a process in six parts: (1) Student interest is sparked to prepare the lesson. (2) The teacher offers an exposition of the principle or idea to be considered. (3) A class discussion is followed by (4) individual reports or aspects of the idea under consideration. (5) Students are then encouraged to observe the results of a change of behavior through commitment to this ideal either through literature or lived experience. (6) Students engage finally in voluntary projects for practice of the ideal, and problem cases are given special attention by the instructor. Morrison's lesson design proved influential on curriculum texts for teacher preparation for the next three decades. *Curriculum Principles and Social Trends* by J. Minor Gwynn, first published in 1943, is a practitioner's approach to curriculum that advocated Morrison's "unit method" through four revisions (until 1969). J. Paul Leonard's *Developing the Secondary School Curriculum* in 1946 also uses Morrison's unit method.

Although Hutchins was not a member of the Department of Education, Hutchins's tenure as president of the University of Chicago was notable in his advocacy of liberal arts education. Rejecting both progressive proposals for educational reform and those who promoted higher education as specialized training, Hutchins envisioned a curriculum that brought young people into conversation with the great thinkers and ideas of Western civilization. In promoting a great books curriculum, Hutchins made the argument that a democratic society would survive only if citizenry were enlightened to the various options that have been proposed relative to fulfilled human living. Suggesting that high school could be condensed if the focus was on building intellectual skills, the last 2 years of high school could be replaced with a college curriculum where students were introduced to the ideas and proposals of Western thinkers ranging from Plato and Euripides to René Descartes and Charles

Darwin. At the University of Chicago, a variation of his plan was enacted as the undergraduate curriculum and elements of this approach were widely imitated by other liberal arts colleges.

Given that Hutchins was a national champion for traditional liberal arts education, it surprised some when he sought out Ralph Tyler to replace Judd in leading the Department of Education in 1938. Tyler had established a national profile as principal evaluator of the Progressive Education Association's comparative study of high school curricula known as the Eight Year Study. As a condition of his appointment, Tyler arranged to have his evaluation team for the Eight Year Study moved from The Ohio State University to Chicago. Tyler became the chairman of the Department of Education and eventually the dean of the Division of Social Sciences.

Tyler's interest in fostering a scholarly construct for curriculum development prompted him to convene with Virgil Herrick a conference in 1947 at the university that assembled some of the most notable writers on curriculum study of the day. The conference offered shared convictions on the character of sound curriculum scholarship but failed to develop tenets to guide curriculum activity and research. Tyler's aspirations were, in part, realized by his own teaching. Tyler expanded a course syllabus into the highly influential volume, *Basic Principles of Curriculum and Instruction*, in 1949. Tyler set curriculum issues in a rationally organized, concisely stated schema, exploring dimensions that arise within each of the issues while largely refraining from taking a position in support of the various proposals for curriculum reform that were contending at mid-century. Tyler raised four categories of consideration for curriculum development: purposes, experiences, organization, and evaluation. Numerous curriculum guides, teachers' editions of schoolbooks, evaluation instruments by accrediting agencies, course syllabi, and curriculum books that were written throughout the balance of the 20th century use Tyler's four issues for organization.

Benjamin Bloom and his associates provided a conceptual structure for stating intended outcomes of a curriculum that was in some ways an extension of the Tyler Rationale in the consideration of the form of educational purpose, yet also reached back to the model proposed by Charters. The learning objective continues to be emphasized in unit and

daily lesson planning. The 1956 taxonomical classification of cognitive objectives gained broad acceptance as a structured approach to identifying knowledge and skills to be attained, and the six cognitive levels (memory, interpretation or comprehension, application, analysis, synthesis, and evaluation) have been committed to memory by many aspiring teachers. The taxonomy has been applied to lesson planning, school curricula, questioning techniques, and skills management systems. Taxonomies in the affective and psychomotor domains followed to provide a full range of skills and knowledge determined to be significant in education.

Thelen, as did Tyler and Bloom, received his PhD at Chicago. He joined the faculty in 1945 and applied the field of group dynamics to curriculum study. Thelen advocated use of observation to inform educational practice and conducted studies in the context of educational practice and community activism, simultaneously promoting reflective deliberation consistent with Dewey's epistemology. His curriculum proposal served as a bridge between Dewey and the existing school curriculum. He argued that school study be integrated into four disciplines: (1) the physical domain, (2) the biological, (3) the social, and (4) the "subjective" or the humanities. Topics are considered in a manner appropriate to the subject of inquiry. Skill development is included as a fifth form of inquiry, intended to assist in facilitating the basic forms of inquiry. Thelen's model incorporated reflective thinking into a modified curriculum structure of existing school disciplines.

In addition to the influence of scholars, the University of Chicago also served as publishing house for the National Society for the Study of Education Yearbooks. Although a range of educational topics were selected as themes for the yearbooks, landmark works on curriculum studies were produced through this publication. Kenneth Rehage, faculty member in the Department of Education, was prominent in the publication of the NSSE yearbook in its last decade at the University of Chicago.

Joseph Schwab literally grew to adulthood at the University of Chicago, coming to the institution after high school. Through the 1940s, he assisted in developing Hutchins's general education undergraduate curriculum. With a background in the sciences, Schwab also served as

instructor in the collegiate program. He served as chairman of the Committee on Teacher Preparation for the Biological Sciences Curriculum Study (BSCS), funded by the Educational Defense Act of 1958, and edited the initial textbooks.

Schwab became a critic of education and particularly curricular study at the end of the 1960s. He viewed student unrest at the end of the decade as a failure in education to engage students in critical consideration of issues of significance. His invited address to the American Educational Research Association in 1969 became infamous for declaring curriculum studies "moribund." Schwab's alternative approach to curriculum scholarship was articulated in "The Practical: A Language for Curriculum." Advancing a position indebted to Dewey's conception of scholarship, he suggested that curriculum shift to practical research of events and situational conflicts. Generalized conclusions are replaced by an effort to solve problems. In later articles, Schwab detailed his call for contextual scholarship that considered the interdependence of four commonplaces of curricular experience: subject matter, learners, teachers, and milieu. Interactions among these factors in problematic classroom encounters create the curricula that actually occur there.

Philip Jackson's 1968 *Life in Classrooms* was a creative study that awakened curricular scholars to the powerful effects of what came to be labeled the "hidden curriculum." Jackson's writing invited readers to observe the power, influence, and the normative structure of the elementary schools that he visited. The study also considered how regularities and social relationships in differing school contexts can affect the lives of learners. While examining the thinking of Dewey and responding critically to the emergence of new directions in curriculum thought, Jackson also conducted a study on the character of teaching, identifying valued elements in the character of the educator. *The Handbook of Research on Curriculum*, edited by Jackson, was a first of its kind as a portrait of curriculum scholarship at the end of the century.

In 1997, the university decided to eliminate the Department of Education and no longer offer a PhD in education, leaving a legacy of influential graduates.

## UNIVERSITY OF ILLINOIS COLLECTIVE OF CURRICULUM PROFESSORS

---

The University of Illinois developed a long-standing tradition as a collective for curriculum studies promoting social foundations and philosophy as a basis for curriculum development, education for furthering democracy and advancement of liberal arts in schools with attention to aesthetics, particularly in the last half of the 20th century. The College of Education made a powerful impact on curriculum theory with important collaboration on curriculum books produced in the 1950s and 1960s by B. O. Smith, William Stanley, J. Harlan Shores, Harry S. Broudy, and Joe R. Burnett; the proposal of Lawrence Metcalf for the social studies curriculum; and contributions of Louis Rubin. Ironically, a more prominent impact on curriculum policy was the diatribe against the life skills curriculum by Arthur Bestor, a history professor at the University of Illinois.

An ambitious new direction for curriculum development emerged in 1950 with the publication

of *Fundamentals of Curriculum Development* by three University of Illinois professors, Smith, Stanley, Shores. Smith had gained national attention as coauthor, with Kenneth Benne, also at Illinois in the 1950s, Bruce Raup, and George Axetelle of a method for forming practical social judgment. *The Improvement of Practical Intelligence* expanded John Dewey's process of scientific deliberation as "reflective thinking" to a detailed model for "democratic social planning." *Fundamentals of Curriculum Development*, a textbook for use in graduate coursework, provided a contemporary overview of curriculum thought emphasizing social analysis in curriculum development, Smith's reflective thinking proposal, and analysis of curriculum's relationship to cultural change. The authors described curriculum development as collective deliberation on determining objectives, selecting content, considering scope and sequence of instruction, and evaluation. Reflecting a social reconstructionist orientation, curriculum development was presented as a social and political process whereby cultural values and goals served as the wider text in determining a school curriculum. Smith and Stanley also joined with Benne and Archibald Anderson in authoring a widely adopted text on social foundations.

Smith joined other University of Illinois colleagues 14 years after initial publication of *Fundamentals of Curriculum Development* to craft a proposal that, though sharing the commitment to the democratic values promoted by Smith, Stanley, and Shores, incorporated new directions in curriculum thought, particularly in basing curriculum theory in educational philosophy. This orientation reflected the interests of his collaborators, Broudy and Burnett in their 1964 curriculum statement *Democracy and Excellence in American Secondary Education*. Broudy was named professor in the College of Education in 1957 and contributed to curriculum thought by fusing insights from Dewey's educational philosophy with existentialism and interest in the aesthetic process in a unique critical perspective. Burnett was also primarily interested in educational philosophy with particular interest in Dewey's social uses of philosophy.

Broudy, Smith, and Burnett presented a "design for schooling" where high school students examine descriptive and valuative concepts, principles, norms, and rules. Broudy, Smith, and Burnett's

criticism of public education was that essential intellectual processes and emotional commitments were being overshadowed in the high school curriculum that focused on facts and concepts. In a previous work, *Building a Philosophy of Education*, Broudy contended potentialities mark the distinctive nature of humanity; developing these potentials fosters the “good life.” Broudy located three essential human purposes endemic to the character of democratic life: (1) self-determination; (2) self-realization, drawing from individual gifts and capacities; and (3) self-integration. Broudy, Smith, and Burnett contended schools should promote the formation of intellectual habits in each person, attending to the cognitive development of learners and the integrity of the valued disciplines.

Bestor was a major voice in the traditionalist revival at mid-century with the success of *Educational Wastelands*. Bestor centered his attack on the life needs movement curriculum, maintaining democracy’s vitality depended on taking the lessons of the culture and presenting them in a methodical, disciplined fashion to young people. Education proceeds systematically to offer students a command of intellectual tools and a store of reliable information. The standard academic disciplines were socially determined according to Bestor. For elementary education, the basic skills of computation, reading, and writing are sufficient to establish the skill base for knowledge acquisition. Specialization begins in high school, but only with assurance that a foundation has been established in general studies. Bestor criticized schools of education as meddling with curriculum when their responsibility was to provide training on effective instruction.

Bestor had the attention of conservative critics, but Metcalf was reshaping social studies as an academic discipline in the U.S. high school. With Maurice Hunt, Metcalf produced a methods text that applied reflective thinking and practical intelligence to consideration of personal and social problems relevant to the lives of learners. Hunt and Metcalf’s text restructured traditional approaches to social studies by crossing conventional academic boundaries, presenting the social sciences as a skill set.

Rubin emerged in the 1960s as a counterpoint to the insistence that academic content drive curriculum development. With J. C. Parker, Rubin

argued that intellectual skills or processes not be subordinate to academic content in curriculum development. Rubin promoted curriculum for individual development and social participation, evident in the editing of an ASCD yearbook dedicated to revision of the life skills curriculum. Rubin’s thinking evolved into an interest in aesthetic thought in education and his volume *Artistry in Teaching*, published in 1984, described teaching as performance with curriculum development being an essential personal dimension of this art.

## UNIVERSITY OF WISCONSIN COLLECTIVE OF CURRICULUM PROFESSORS

---

The Department of Curriculum and Instruction in the College of Education at the University of Wisconsin–Madison has influenced curriculum studies since its rise to prominence in the 1950s. Virgil Herrick and Edward A. Krug, helped to establish new directions in curriculum theory and history, and these areas of study have continued to be developed through the work of Michael Apple and Herbert Kliebard since the 1970s.

Herrick’s first contributions in curriculum thought came after World War II, offering direction on design of the elementary school and curriculum and collaborating with Ralph Tyler. Having completed all of his degrees at the University

of Wisconsin, Herrick returned to Wisconsin in the program for Preparation of Elementary School Teachers in 1948 after 6 years at the University of Chicago. Herrick remained at Wisconsin until his death in 1963. His considerations of the structure and designs of school curricula, instructional planning, and curriculum research and evaluation provided various strategies for curriculum improvement. Herrick offered insight on how curriculum development can have a rationale and determined structure and yet attend to child needs, interests, and differences. He contended curriculum theory has value when tested in classroom instruction to determine effects. Bridging the professional task of curriculum construction to attend to the individual learner characterized both his scholarship and teaching career at Wisconsin. Although his own work was decidedly focused on curriculum structure and empirical analysis, two of his most notable students, James B. Macdonald and Dwayne Huebner were major contributors to the redirecting of curriculum theory away from a positivistic orientation in the 1960s and 1970s. Macdonald took a position at the University of Wisconsin at Milwaukee and developed a model of curriculum inquiry centered on the recognition of mythopoetic language as a source of insight in understanding meaning in curriculum. Macdonald, like Herrick, hoped that theorizing could translate to change in the practices of schools, making them places of liberation in opening up discussion and interaction. He developed a theoretical model that describes curriculum as enactment. Huebner, who taught at Teachers College, offered one of the first major arguments for expanding language discourses used to understand curriculum and gave particular attention to politics, aesthetics, and spirituality.

Krug was an important contributor at the University of Wisconsin from the late 1940s through to his retirement in the 1970s. Although most associated with his landmark history of the U.S. high school in two volumes, Krug influenced curriculum studies with an important synoptic text, *Curriculum Planning*, first published in 1950. Krug began his scholarly career writing high school social studies texts and, like Herrick, emphasized translation of deliberations to effective practice in his approach to planning. He emphasized localized decision making and integration of curriculum

development with instructional practices. This practitioner orientation was central in a book he produced in 1957 on the administrator's responsibilities in curriculum planning.

Kliebard, using history as a lens for critiquing curriculum scholarship and practice, developed widely adopted categorizations for better understanding alternatives in curriculum thought. Kliebard's *Struggle for the American Curriculum* posited four historical curriculum perspectives as competing models of curriculum study and development in the United States in the 20th century: humanist, social efficiency, developmental, and social meliorist. This classic text underwent revision and update, with Kliebard complementing intellectual history with data on school practices. Kliebard also expanded on options in understanding of vocational education in the early 20th century.

Apple, a student of Huebner at Teachers College, began his career at the University of Wisconsin as a professor in the Department of Curriculum and Instruction in 1970. Apple advanced inquiry into the ideological ramifications of curriculum in schools with his enduring work, *Ideology and Curriculum*. Influenced by the theoretical construct of neo-Marxist scholars such as Antonio Gramsci, Apple's analysis of curriculum employed an economic-political lens, focusing on the hegemonic domination of U.S. public schooling by competitive capitalism and maintenance of class structure. His later inquiries considered the interaction of education and political power in schools and the political economy of textbooks. In the 1990s, Apple speculated on the impact that official knowledge and cultural politics have on the restriction of democratic education. Apple retained a reform perspective in the promotion of democratic practices in schools, appreciative of progressive efforts at schooling. His later scholarship was characterized by openness to the contributions made by postmodern thought and how gender and racial difference can provide alternative and complementary understandings of power relationships.

Other faculty at the University of Wisconsin contributed to curriculum studies focused on advancing understanding and implementation of curriculum responsive to politics, teacher education, and cultural diversity. Thomas Popekewitz contributed to understanding of politics and

teacher education, teacher formation, and school reform in historical and international contexts.

Gloria Ladson-Billings's popular portrait of effective teachers of African American students, *Dream-Keepers*, called attention to culturally responsive curriculum and instruction. She subsequently produced work on critical race theory and the practices of teaching to culturally diverse students. Carl Grant contributed substantially to the practices of teaching in a culturally diverse society both through teacher preparation texts and a foundational perspective on options in multicultural education that Grant developed with Christine Sleeter.

## UNSCHOOLING

---

*Unschooling* is often considered a form of homeschooling; however, it differs significantly from both schooling and homeschooling. Unschooling is derived principally from the work of John Holt. It refers to a progressive form of growing without schooling and is based on the premise that the bureaucracy of schooling incorporates many impediments to learning. Holt and his associates founded a magazine and an organization called *Growing Without Schooling* that encourages parents, children, and interested others to form

relationships in which they grow without the impositions of schooling that can be counterproductive to interests and needs of learners.

Holt became well known in the 1960s for his best-selling books, *How Children Fail* and *How Children Learn*. Both were written as journals of his observations and interpretations of interactions with children. During the 1970s, he wrote books of ideas for schoolteachers to reach children while crediting their own insights into learning that best meets their needs. By the late 1970s and early 1980s, Holt became disenchanted with the potential of schools to meet students' needs; thus, he emphasized the need to create alternatives to schools. Through *Instead of Education* and especially via *Teach Your Own*, he fully developed his position on unschooling. He provided compelling reasons for why parents should take students out of schooling to develop educational experiences *with* them. He carefully emphasized, contrary to mainstream homeschooling, that the point of unschooling is to create educational experiences that are not based on identification deficits of learners, that do not serve the interests of power-wielders at the expense of personal and public interests, and that do not incompetently or autocratically indoctrinate learners.

Put more positively, Holt couches his advocacy in the following: the civil liberties of children, responsibility of parents and children as central to meaningful education, and protection of children from harm. He counters objections to unschooling, discusses its political implications in fostering democracy, and presents strategies for taking students out of school in view of potential resistances. Holt elaborates on ways to build educational experiences on children's interests, live with children and explore together, and create opportunities for growing in the home and community. He advocates approaches to learning without formal teaching and building on the most important work in children's lives: play. Holt discusses ways for parents to develop networks, overcome problems, deal with legal issues, and respond to criticism from the schooling establishment. Finally, he provides a range of resources for those who are interested in pursuing unschooling.

More recently, John Taylor Gatto also serves the unschooling dimension of homeschooling. His 1991 book, *Dumbing Us Down*, is a major

critique of schooling based on more than 30 years of experience and multiple awards as New York State and New York City Teacher of the Year. His work, like Holt's before him, proposes that parents, families, children, youths, and interested others need to develop curricula and not rely on the institutionalized and generic curriculum of schooling. Gatto has garnered much attention as a critic of schooling and an advocate for alternative, grassroots forms of education to overcome schools' inadequacies. In this sense, unschooling is related to deschooling proposed in the early 1970s by Ivan Illich. Moreover, it complements the transition within the curriculum field (identified by William Pinar and his coauthors) from emphasis on curriculum development to focus on understanding curriculum as multiple social forces: political, racial, gender, phenomenological, international, theological, aesthetic, biographical, autobiographical—as well as institutional factors within schools.

Unschooling and its deschooling relatives can be seen as practical instantiations of the deinstitutionalization of curriculum studies.

## VALIDITY, CATALYTIC

---

Catalytic validity is a category of validity researchers use to evaluate whether qualitative research intended to spur social change accomplishes its objectives. *Validity* refers to whether methods undertaken in quantitative or qualitative research examine what they are intended to examine and thus produce credible findings. The criteria that determine whether a given study is valid differ based on which philosophies and theories guide the research, the research purpose, and whether the research is qualitative or quantitative. Historically, qualitative researchers have adapted traditional scientific criteria associated with quantitative research to establish qualitative research as valid. Researchers have used such methods as systematic data collection techniques, triangulation, and multiple coders to reduce researcher bias and ensure valid findings. In recent decades, as forms of qualitative inquiry have proliferated, many researchers have questioned the very standards used to judge what constitutes “good” research and “legitimate” knowledge historically, including the concept of validity. Some researchers have argued the traditional criteria used to establish validity are not appropriate for all forms of research and have proposed an array of new types of validity better suited to their theories and purposes. Catalytic validity is one such measure. As the term implies, *catalytic validity* refers to the degree to which a given research endeavor intended to spur personal and social transformation serves as a successful

catalyst for that transformation. Researchers in the field of curriculum studies working within the “critical” research tradition have used catalytic validity and other transgressive forms of validity to evaluate whether research intended to raise consciousness, reform curriculum, or spur student activism accomplishes these goals.

Catalytic validity is embedded in a theory of research that views research as potentially transformative for researchers and participants alike. In this approach, research is not conducted simply to gain information about the social world, and researchers cannot and should not remain neutral in the process of inquiry. Methodologists (those who study theories and methods of conducting research) draw the concept of catalytic validity from educator Paulo Freire’s notion of “conscientization” in which heightened critical consciousness serves as the basis for personal and social transformation. Researchers can serve as active change agents in the conduct of inquiry, striving to raise participants’ consciousness about social inequities and prompt actions that lead to more equitable educational practices. Critical researchers can also transform the research process by refusing the stance of “research expert” studying people who are mere “objects of research.” They can design collaborative research *with* and *for* participants who contribute to collecting, analyzing, and interpreting data.

Unlike traditional forms of validity, catalytic validity is not achieved through creating and following a checklist of standard criteria to demonstrate research credibility. As part of a transformational

research design, catalytic validity charges researchers with the responsibility of reflecting on the research process and remaining vigilant to their research purpose of achieving transformative and emancipatory ends. To achieve those goals, research assessment might include reflection on the following questions: How was the research designed to disrupt traditional power imbalances in the research process and create collaborative relationships between researcher and participants? How did the research transform both researcher and participants? How did the researcher and group members' consciousness evolve during the study? Which concrete actions and improvements resulted from the research? How did the curriculum developed through the research process increase self-determination of or improve conditions for the specific students and teachers that participated? Designing research studies to document these processes can contribute to rigorous and transformative research.

Research in curriculum studies conducted from a feminist, critical, participatory, or action orientation provides opportunities to refine, reconceptualize, and apply the concept of catalytic validity in practice. Such research design requires investigators to remain critical of their practices so as not to celebrate superficial changes or impose their own vision of change on research participants. Scholars associated with the field of curriculum studies have used catalytic validity in a variety of contexts: adult education, rural villages, teacher education programs, online courses, special education programs, English as a second language and women's studies courses, and tribal ecology and management programs, among others. For example, curriculum researchers have used catalytic validity to determine that research involving marginalized students in collecting data can expand their sense of identity and agency. Others seeking to develop culturally relevant curriculum in American Indian communities have involved tribal members as co-researchers in data gathering and analysis; charted increases in communication, critical consciousness, and engagement as research progressed; and witnessed the implementation of curriculum and policy that emerged from the research. Catalytic validity is one method among many that curriculum researchers can use to increase research trustworthiness in projects intended to prompt participant activism,

spur context-specific change, and implement curricular reform.

## VALIDITY, CONSEQUENTIAL

---

Validity is one of several technical qualities that are attributed to the inferences drawn from measures of psychological, behavioral, and physical phenomena. Validity is the degree to which empirical evidence and theory buttress test score interpretations. Along with reliability, validity is regarded as a critically important attribute of test scores. Validity and reliability are initially addressed during the development of a test and are further refined and documented throughout its life using information from newly conducted studies and logical and statistical analyses. Claims about the performance of an individual, project, or program that are based on test scores that lack evidence of validity are considered unsound. Since the mid-1950s, the concept of test validity has been reconceived several times. The focus of this entry is consequential validity, which is one of six aspects of validity that are regarded as criteria or standards that can be applied to all educational and psychological measurement. Introduced by Samuel Messick in 1995, consequential validity focuses on the social values in test interpretation and use.

During the past 60 years, test experts have focused on clarifying the concept of validity. Lee Cronbach is regarded as having broadened the concept by identifying four aspects that test developers and consumers needed to consider: content validity, concurrent validity, predictive validity, and construct validity. Subsequently, predictive and concurrent validity were combined into what is referred to as criterion validity. Such conceptual refinements continued for four more decades, during which the concept of validity evolved and culminated in Messick's article on the validity of psychological assessment. Messick argues that validity is best treated as a single construct with six "aspects" that address issues implicit in the concept of validity: content, substantive, structural, generalizability, external, and consequential. Messick believes that all of these aspects are unified within construct validity. In 1999, the *Standards for Educational and Psychological Testing* organized the conceptualizations of validity that had been generated over the years and asserted that there were five types of validity. These five types integrated each of Messick's six aspects and disregarded the earlier conceptualizations of three separate types of validity—content, criterion, and construct.

Both the intended and unintended consequences that occur from the interpretation and use of a test provide evidence about a test's validity. Such evidence needs to be collected immediately following the use of the test and over the long term. Consequential validity studies focus on how test score interpretations contribute to sources of invalidity with regard to bias, fairness, and distributive justice. Value implications of score interpretations are examined as a basis for action as well as the actual and potential consequences of the test use. For example, consider the long-term social consequences of a school district using a K–6 science curriculum that includes end-of-unit assessments composed of narrowly focused, multiple-choice items. Such an assessment relies only on recall and recognition of facts and principles, but does not assess the ability to predict, explain, evaluate, or conduct scientific inquiry. The use of such an assessment can have long-term negative consequences on students' learning. Students who learned science using this approach may not be well-prepared for the middle and high school

science program, and their engagement in these science courses may be reduced and ultimately diminish their opportunity to acquire employment opportunities in high-paying, technically skilled industry sectors. Attention to consequential validity demands that evidence of positive or adverse benefits of test scores be accrued and examined. Adverse impact of the test can result from construct underrepresentation or from construct-irrelevant variance. Low scores on a test should not occur because the test did not represent all the key content associated with an important topic or that there was something irrelevant that interfered with the individual's ability to demonstrate what they know. Students with disabilities, English language learner students, or ethnic and low-income groups are likely to suffer more adverse impacts as a result of construct underrepresentation or construct-irrelevant variance.

## VALIDITY, CONSTRUCT/CONTENT

---

A construct (e.g., mathematical problem solving, reading comprehension, intrinsic motivation) is any abstract trait that an examiner or researcher intends to measure. Assuring the accuracy and integrity of measures of constructs is essential. Content validity contributes to the integrity of

measurement of a construct through the association of the items in a test with a specific content domain. Construct validity builds additional evidence for measurement integrity based on determining the degree to which the scores on a test appropriately reflect a construct of interest.

Validity is the most critical component of measurement integrity. Simply defined, measurement validity is the degree to which meaningful inferences may be drawn from test data. Although measurement validity is a unitary concept, social scientists have developed a variety of approaches for gathering validity evidence, including content-related and construct-related approaches. Assessment of content-related validity is extremely important in test development and is not to be confused with “face” validity (i.e., the degree to which the content of test items appears *prima facie* to reflect a content domain). Face validity has typically been treated pejoratively by experts in the field of social science measurement compared with the process of content validation, which is considered an integral part of instrument development.

Content validity assessment requires a thorough review of a test’s content by individuals expert in the content area. Content-related validity evidence may be established in various ways. A test developer may, for example, develop a two-dimensional “table of specifications” with particular elements of the content domain defining the rows and essential skills to be mastered defining the columns. Test items are developed to reflect the interaction of content and skills represented by each cell of the table. The content domain might be defined by an established curriculum, a textbook, a scope and sequence outline, or some similar document. Alternately, a panel of curriculum experts may be called on to render informed judgments about content validity. If the test items are deemed by the panel of experts to provide an adequate sampling of the domain, the test may be considered to have content validity. Because content validity is based on test items rather than on test data, it is appreciably limited in its empirical value.

Once content-related validity evidence has been established, data are collected from one or more relevant samples with the goal of gathering construct-related validity evidence. Construct validity is predicated on the assumption that an observable behavior measured by a test item will

correspond with, and be representative of, a latent construct of interest to the examiner. Responses to test items are assigned numerical values (i.e., scores), and these scores become the focus of construct validity studies. Typically, a body of diverse empirical evidence is required to support construct validity, including one or more of the following:

- *Convergent validity*—correlations between scores on the measure of interest and scores on a more established measure known to effectively measure the same construct. Generally, moderate to high correlations would be said to provide evidence of convergent validity.
- *Discriminant validity*—correlations between scores on the measure of interest and scores on a measure of a different construct. Discriminant validity coefficients should generally be smaller in absolute value than convergent validity coefficients if the two types of coefficients are calculated in the same study.
- *Multitrait-multimethod (MTMM) matrix*—a systematic procedure for simultaneously examining convergent and discriminant methods of validity evidence when two or more constructs (traits) are measured by two or more distinct methods. For example, a researcher might assess both motivation and anxiety of a group of research participants using both observations and traditional (pencil-and-paper) instruments. Correlations of scores on all measures would then be tabulated in an MTMM matrix to determine the degree to which (a) various measures of the same constructs produce similar results (convergent validity), (b) measures of different constructs produce disparate results (discriminant validity), and (c) a given method of measurement (e.g., a self-report questionnaire) produces similar results across different constructs (to test for “methods” effects).
- *Factor validity*—intercorrelations among scores on all items in a test followed by extraction of common factors that account for the correlations. Each factor represents a given construct underlying the items. Factors are named based on an examination of the content of all of the items that are appreciably correlated with a given factor.

Unlike content validity, which is test specific, construct validity is data specific. Hence, it is

important to build construct validity evidence over time with different samples under different conditions. It is erroneous for a researcher to assume blindly that a given instrument will yield valid data at a particular point in time with a sample of interest. At minimum, researchers should determine whether a given sample is similar enough to other samples that have yielded valid data. When possible, construct validity estimates should be established for the data in hand. Failure to provide some evidence of construct validity evidence may question the findings of an otherwise well-designed curriculum intervention study. Conversely, providing evidence of construct validity builds confidence in research findings and facilitates evidence to support or disconfirm important educational theories.

## VALIDITY, EXTERNAL/INTERNAL

---

External and internal validity are crucial to the success of experimental studies in curriculum. Results of a study are said to be externally valid if inferences can be confidently made from the study's sample, either to a particular target population or across various populations and settings. By contrast, internal validity has to do with the degree to which observed differences across groups on a dependent (outcome) variable are the direct result of the manipulation of the independent (treatment) variable. Hence, external validity is concerned with *generalizability of results* whereas internal validity is concerned with *plausibility of causal inferences*.

### External Validity

External validity may be discussed in terms of generalizability of findings of a given study to (a) a specific population (i.e., population validity), (b) across settings or from one environmental condition to another (i.e., ecological validity), or (c) across occasions (i.e., temporal validity). A researcher interested in external validity might ask questions such as these: Can results obtained from a particular sample be replicated with a second sample drawn from the same population? Are results achieved in 4th-grade classrooms generalizable to middle-grade students? Are promising results obtained early in the school year generalizable to occasions later in the school year? A common misperception among researchers is that evidence of statistical significance equates with evidence of generalizability. Statistical significance only informs about the likelihood of a null hypothesis under the assumption that the sample represents the population. Finding a statistically significant result neither guarantees the goodness of a sample nor makes promises about external validity.

Any factor that challenges the relationship of the findings of a given study to the population(s) or setting(s) of interest is considered a threat to external validity. A researcher might, for example, fail to adequately specify a treatment variable, resulting in the lack of integrity of the treatment. Likewise, unintended treatment interaction effects (e.g., pretest-treatment interactions, multiple-treatment interactions, selection-treatment interactions) can affect participants to the extent that it is difficult to isolate the effects of the treatment. External validity is also threatened by various experimenter effects. For example, high school students involved in a study might react differently to a male versus a female teacher. Further, researchers may unwittingly allow their own attitudes or expectations to affect their interaction with the research participants, resulting in experimenter bias effects. Finally, the way a study is conducted might prompt various unintended reactions from participants, such as the Hawthorne effect, the John Henry effect (compensatory rivalry), or placebo effects, that modify participant behavior and contaminate study outcomes.

Replication of results across multiple studies is crucial in building a case for external validity.

However, it is possible to gain preliminary estimates of replicability of results within the limits of a single study by splitting or reconfiguring the sample and recomputing results across these sample subsets using “cross validation,” “jackknife,” or “bootstrap” procedures. Whereas true research replication remains the gold standard for establishing evidence for external validity, use of these sample splitting procedures increases the external validity evidence for a single study. Evidence of external validity is further enhanced when the researcher employs careful description of the sample selection procedures, research methods, and data collection procedures employed. Finally, external validity is enhanced by reporting of statistical effect sizes. These indices provide evidence of strength of findings and extend the usefulness of other commonly used statistical indices such as descriptive statistics and statistical significance test results.

### Internal Validity

As previously noted, internal validity is a factor of the degree to which research participants’ performance on outcome (dependent) variable(s) is a direct result of the treatment(s) received (independent variables) and not on other factors. Curriculum experiments are best conducted in naturalistic settings, such as classrooms. Classrooms produce special challenges to establishing experimental controls to ensure internal validity. For example, an experiment might be conducted to determine the effects of teacher praise on students’ reading fluency. The school might also be implementing a new reading curriculum during the same time period as the study. In this case, it would be difficult to isolate the effects of the independent variable (praise) on the dependent variable. As this example illustrates, it is important that researchers document any perceived threats and indicate what steps were taken to compensate for the presence of these threats.

Specific events that might occur within experimental settings that could have a deleterious impact on internal validity may be related to history (events occurring within a study that are not a part of the intended treatment), maturation (natural intellectual or physical growth of participants during the course of a study that might affect

performance), testing (ability of pretests or other assessments completed by participants early in a study to affect later performance), instrumentation (limits of instruments or procedures used to collect valid or reliable data on important intermediary or outcome variables), statistical regression (probability that participants who receive extremely high or low scores on an initial measure of a variable will score closer to the mean on successive measures of the variable), and mortality (loss of sample participants due to withdrawal from a study before its completion). Presence of any of these factors may yield “rival hypotheses” that challenge the assumption that the independent variable acted alone is producing research outcomes.

## VALIDITY, TRANSGRESSIVE

---

Transgressive validity is a category of validity qualitative researchers have developed in recent decades to reconceptualize what constitutes “good” research and “legitimate” knowledge and the criteria used to evaluate that research. “Validity” is a common tool researchers use to ensure their methods examine what they intend to examine. Unlike traditional forms of validity, transgressive validity is a technique aimed as much to challenge traditional authorizing criteria, to stimulate thinking about how knowledge is created, and to generate new research practices as it is intended to evaluate whether transgressive research accomplishes its goals. Historically, researchers have used particular

techniques to ensure their findings correspond with the social phenomenon studied. As the landscape of qualitative research has expanded, researchers have found conventional forms of validity inappropriate for evaluating their studies and have developed alternative criteria for analyzing how knowledge is produced and legitimated. Feminist methodologist Patti Lather includes the categories of ironic, paralogic, rhizomatic, and voluptuous in her poststructuralist conceptualizing of transgressive validity; other forms that curriculum scholars use to expand accepted validity categories include catalytic, crystallization, communicative, and pragmatic.

The criteria researchers use to determine whether research is valid differs based on which theories guide the research, the methods used, and the research goals. Historically, qualitative researchers working within conventional research traditions have adapted quantitative validity criteria to qualitative ends. These techniques include triangulation (originally meaning multiple methods but expanding to include multiple data sources, theories, and researchers), face and construct validity, the reduction of researcher bias, and systematic data collection. These techniques remain common today. However, the 1970s ushered in a significant period termed the “crisis of representation” in which scholars began questioning long-accepted beliefs about knowledge, truth, and the capacity for research to capture the complexity of the social world. This “crisis” spurred a rich intellectual ferment that led to new forms of research, new ways of representing research, and new methods for legitimating that research, including validity. Some scholars have argued that the quantitative origins of “validity” necessitate abandoning the concept to develop other methods of establishing credibility. Others maintain the term conveys a degree of rigor worth preserving and expanding.

Transgressive validity offers researchers alternatives to what some see as fruitless quests to seek correspondence between “research findings” and “reality” and prompts the development of other methods for conducting and legitimating research. For example, ironic validity refers to how effective research is in casting doubt on the possibility of representing the complexity of the social world. Research gains legitimacy if researchers simultaneously highlight how they make meaning of the

curriculum or classrooms under study while demonstrating that meaning is partial and unreliable. In this view, the researcher might use multiple textual forms to interpret the object of inquiry and convey that, ultimately, it can never be represented beyond that role. In contrast, paralogic validity, drawn from the philosopher Jean-François Lyotard’s work, refers to how effectively research resists the tyranny of consensus and highlights differences, uncertainties, and contradictions. In this transgressive form, multiple interpretations of data that emphasize the complexity of meaning making and undermine the researcher as final authority might enhance credibility.

*Rhizomatic validity* refers to how rigorously the research displaces conventional hierarchies and highlights networks and complexity. Rhizomes are systems that share above-ground roots, multiple underground stems, and various branches and bulbs. The rhizome metaphor captures the transgressive impulse to map networks and unsettle dominant systems that emphasize order and stability and to open up possibilities for research practices yet to come. Lather’s category of voluptuous/situated validity refers to an investigator’s success in pursuing excessive and risky projects that disrupt universal claims based on masculine understandings of science and highlight situated and embodied accounts. A researcher claims voluptuous validity through relentless self-reflexivity, partial and tentative accounts, and multiple textual forms (such as poetry and social science) to highlight openness and possibility.

Transgressive forms of validity have served narrative scholars seeking alternatives for validating autobiographical and biographical narratives. Other forms of validity that “transgress” traditional understandings of research credibility are: catalytic validity rooted in the tradition of critical theory that seeks evidence beyond the traditional checklist of criteria that research intended to spur social change does so; crystallization, which sociologist Laurel Richardson uses to contrast the complex and multisided interpretations that crystals represent with the limited and fixed triangle image “triangulation” represents in standard validity criteria, communicative validity in which dialogue contributes to establishing interpretive authority, and pragmatic validity, which deems interpretations valid if they prompt action.

Researchers theorizing transgressive validity do not seek to prescribe new forms of legitimacy but to open possibilities for thinking about research and authority.

## VOCATIONAL EDUCATION CURRICULUM

---

Contemporary vocational education is oriented to preparing people to perform successfully in the workforce. Its roots stretch back thousands of years. Once the U.S. vocational education movement emerged in the late 19th century, educators have used diverse curricula to prepare citizens for work. The field of vocational education has evolved from scattered 19th-century manual training initiatives focused on work processes and moral reform to comprehensive and systematic curriculum focused on labor needs and concrete outcomes. Workforce education includes varied curricular strategies, educational philosophies, and cultural beliefs. Yet an enduring principle that distinguishes it from other fields is its close relevance to the world of work. Vocational educators argue that the diverse activities that constitute vocational curriculum should be directly relevant to a future worker's skill development and occupational future. Indeed, vocational curriculum is considered effective if it is responsive to local and national occupational needs, dynamic as fields and technologies change, driven by occupational and demographic data, focused on concrete

outcomes, oriented to the future, and responsive to assessment. Whether oriented to the adolescent or adult learner, whether in vocational or secondary schools, these goals, as well as federal funding, shape the content and delivery of curriculum.

### History

The roots of contemporary vocational curriculum stretch back thousands of years. Through modeling, direct instruction, and imitation, youth in diverse cultures have learned from their elders to gather food, build shelter, and create goods. In Egypt, students worked as apprentices with skilled scribes as early as 2000 BCE. Elsewhere, artisans taught such specialized skills as stone masonry. During medieval times, “journeymen” who owned tools traveled to perform various jobs, formed guilds to share secrets of their craft, and controlled how many workers could join their ranks. During the American colonial period, apprenticeships became a common form of work education governed by the legal system. Artisans provided long-term guidance to those learning a skill or a trade. This educational relationship required years of servitude from apprentices, including poor and orphaned youth, who were often exploited for their cheap labor.

Significant changes in the U.S. economy and the structure of work in the late 19th century stimulated lasting changes in the relationship of schooling to work that continue to shape curriculum today. Large factories concentrated in urban areas replaced small businesses and family farms as the primary instruments of economic production. As workers' jobs were deskilled into repetitive assembly line tasks, managers began supervising the labor of workers and artisans who had previously worked independently. Apprenticeship seemed an increasingly irrelevant model to prepare workers for the new industrial system. Reformers and business leaders grappling with the sheer need for workers advocated new educational strategies. During the 20th century, educators developed supplementary manual training courses and programs, sought funding for vocational education, integrated vocational courses and tracks in schools, and created a system of career and technical programs that today serve millions of students nationwide.

## Key Components

Because vocational curriculum is oriented to preparing people to perform successfully in the workforce, the learning activities and experiences that constitute curriculum focus on both *process* and *product*: educational processes that occur during schooling and the cumulative results of those processes once schooling is complete. In workforce education, students do not learn math simply for the sake of math. Content should have direct relevance to the responsibilities and standards expected in the completer's given work role. Curriculum might include work ethics, work habits, safety, applied academics, and legal issues. Curricular strategies also produce other valuable but more elusive outcomes such as the value of hard work, an appreciation for collaboration, a sense of satisfaction, and feelings of pride and respect for the profession for which students are being trained.

A unique aspect of vocational curriculum is its accountability and responsiveness to community, regional, and national occupational needs. Curriculum changes as educators assess labor needs, technological advances, and occupational shifts. In addition, funding mandates specific offerings, facilities and equipment, populations of students, and teacher credentials. Ideally, partnerships between vocational schools and local industries should be symbiotic and robust so that schools respond to employers' needs and industries provide internship and employment opportunities for graduates. Larger national concerns such as technological development and global competition also shape curriculum. Beginning in the 1960s, increasing concern for the nation's ability to compete in a global economy led to the development of the Carl D. Perkins Vocational and Applied Technology Education Act of 1990 (Perkins II) and the School-to-Work Opportunities Act of 1994. Perkins II funded creative and cooperative curriculum intended to prepare workers for fast-paced and changing working conditions. Curriculum emphasized flexibility, adaptability, and math, science, and communication skills. Unlike previous legislation that supported the bifurcation of vocational and academic programs, the School-to-Work Acts required programs to link school and work-based learning to receive federal funds. Educators continue to be held

accountable to particular state and federal standards to receive funding.

Vocational educators use varied curricular strategies and frameworks to facilitate learning. School-based approaches, work-based approaches, models, simulation, on-the-job training, individualized learning, and competency-based education (CBE) are a few of many tools available. Varied curricular systems are also available to help educators create and deliver curriculum such as developing a curriculum approach (DACUM), the thematic curriculum framework, the integrated system (ISWEC), or instructional design systems (ISD). DACUM, for instance, is an analytic process to help educators develop curriculum using field specialists who provide profiles of skill sets needed for a given occupation. The thematic curriculum framework provides contextualized learning organized around broad themes rather than specific tasks, courses, and skills. It provides specific and comprehensive industry content ("all aspects of industry") relevant to a particular theme. The ISWEC divides content into three categories that range from core knowledge useful for a broad spectrum of jobs to specialized knowledge for target occupations. This system is intended to accommodate diverse learners as they decide over time which field to pursue. In an ISD curriculum, educators focus on assessing the needs of a given context or developing a problem-solving approach to maximize employee performance.

Vocational goals and objectives shape curricular content. For example, "school-to-work" initiatives (1990s) are designed to facilitate transitions from schooling to work. To create "work-ready" students, educators might use school-based and work-based learning; modularized, individualized, or competency-based curriculum; or a variety of academic and vocational integration strategies. School-based learning might include simulations of work settings in laboratories and examples of scenarios drawn from actual work settings. Workplace learning might involve tours, interviews, simulation of tasks, internships, or on-the-job training. Educators might use modularized instruction to organize curriculum around a self-contained unit of exercises and resources rather than a particular subject or timeframe. Systematic individualized instruction is another option, orienting the learning environment, curricular content, media, and

teaching tools to each student's needs. This approach is particularly challenging for instructors negotiating multiple students' capabilities and instructional needs but can be highly effective for facilitating student progress. In addition, programs might seek formal integration of vocational and academic learning. Such efforts include altering content of both academic and vocational courses to ensure cohesion and relevance and greater integration of high school technical programs in which students pursue specific occupational training in off-site facilities.

Equipment and physical space are also key components of vocational curriculum. During the early vocational movement, educators often took great pains to separate vocational and academic spaces to symbolically demarcate their different goals. They created workshops, laboratories, housekeeping cottages, and separate training schools to preserve the borders of vocational space and to house specialized equipment and materials necessary for training. In current day, students are sometimes bused from high schools to separate facilities to prepare for work. The X-ray machines, hospital beds, mannequins, hairdryers and cosmetology stations, electrical equipment, computer labs, ovens, welding equipment, engine parts, construction supplies, and drafting boards needed for any given vocational program can consume significant space. Their maintenance, transport, and replacement are costly. Moreover, technological developments and workforce changes require educators to update equipment and materials frequently.

Vocational educators also consider data on workforce trends, community demographics, labor needs, instructional costs, and the effectiveness of classroom learning activities important to their mission. Educators cannot create relevant curriculum based on abstract ideas about work trends or demographic shifts. They must rely on population trends in a given geographic area, the age of residents, and developing fields of employment to plan curriculum and programs that will link graduates with local jobs. Surveys, interviews, and statistics may elicit relevant data for curriculum planners to project costs, plan realistic programs, and revise curriculum that fails to meet workforce needs. Such data also shapes policy.

Assessment is another component of vocational curriculum. Curriculum is created, implemented,

and altered based on assessments of how well learning activities help students perform particular skills. A favored educational approach that facilitates assessment is outcomes-based education or CBE. This model defines competencies as skills and attitudes essential to success in a particular work role. Instructors use competency catalogues (detailed lists of tasks for particular occupations) and competency profiles (student skill records) to determine competencies and plan curricula. The criteria to determine competencies are specific, explicit, sequenced, and individualized to the extent that students can develop competencies at a pace appropriate to their skill levels, background knowledge, and learning styles. Also, the CBE model advocates measuring outcomes to ensure curriculum is effective. For example, however effectively a student writes an essay on the process of fixing an engine problem, a measurable outcome of a CBE module on engine repair is the student's ability to actually fix that problem in school or in an employer's machine shop. In this five-step model, a task is analyzed, a performance standard is identified, instruction strategies are linked to desired outcomes, instruction is delivered, and curriculum is assessed. Curricular outcomes deemed effective might include assembling a particular tool, correcting a mishap in hair dye, or smoothly inserting an IV into a patient's arm.

### Debates That Shape Vocational Education

Significant philosophical debates shape vocational education. Historically, while advocates of "scientific management" sought to produce efficient workers and tightly link classroom practices with industrial efficiency, progressive educators hoped vocational curriculum would heighten workers' consciousness of the meaning of their labor and incite labor reform. Similar debates continue today. For example, some educators decry what they see to be vocational education's erosion of humanistic curriculum that renders preparation for work the primary purpose of schooling. Others advocate democratic vocational education rather than training, arguing that much of workforce preparation has focused on compliance and imitation (training) rather than critique and innovation (education). Critical educators argue that rather than fitting human beings to workforce needs, democratic

vocational curriculum should aid students in choosing careers, developing critical thinking skills to keep a job and improve working conditions, understand the larger context of their work, and consider how society, politics, media, and capitalism construct the value, organization, and rewards of “work.” In this view, vocational education should not be limited to utilitarian and applied objectives. It should foster students’ ability to ask critical questions about social and economic inequities and to work for a better future.

Critical scholars have also delineated a “hidden curriculum” that shapes vocational education. This phrase refers to the subtle behavioral directives and value-laden messages communicated to students alongside overt lessons in machinery, carpentry, or sewing. While students learn new skills, they also learn obedience, punctuality, cleanliness, order, and an orientation toward work. Another example of this curriculum that sustains social stratification is the process of “tracking” students. Scholars have identified educators’ tendencies, both conscious and unconscious, to direct students on the basis of their race, class, or gender to particular occupations at the expense of other life choices. The abilities and characteristics educators imagine in their students can thus shape how educators guide and direct student development.

Other debates center on curricular delivery. Educators debate the respective advantages of formal classroom training versus on the job training and whether curricular depth or breadth is most advantageous for students. For example, some advocate a broad skill set students can apply in a range of occupations (sometimes termed “clustered” programs). This approach ensures flexibility in an unpredictable job market. Others laud specialized skill sets for specific occupations. This position emphasizes depth of knowledge. Educators continue to wrestle with changes in the world of work, technological development, state and federal funding, and varied student needs and abilities in developing vocational curriculum that can best prepare citizens’ for their diverse roles.

## VOCATIONAL EDUCATION CURRICULUM, HISTORY OF

---

The U.S. vocational education movement emerged in the late 19th century in response to profound economic changes and leaders’ increasing conviction that schools must prepare workers for the nation’s new economic structure. This belief—that schools should be linked with work—reflected a fundamental shift in citizens’ vision of schooling in a democracy. Although educators’ efforts to teach basic skills and champion the values of industry and productivity have always had “vocational” implications, reformers in the late 19th and early 20th centuries sought to integrate work training into schools. Institutionalizing worker preparation, like other educational reform efforts, reflects U.S. citizens’ enduring belief that schools can and should address a variety of complex social issues, including workforce needs, poverty, unemployment, and class tensions. Vocational education (termed *workforce* or *career and technical education* today) encompasses diverse approaches and philosophies. Although some reformers consider work education essential, others characterize it as a form of social engineering that directs certain youth to professions and others to manual labor. In this view, “tracking” youth to particular occupations is antithetical to democratic schooling. The history of vocational curriculum thus reflects a tapestry of U.S. citizens’ ideals, hopes, and fears as they have sought to prepare diverse citizens for roles in an industrialized and pluralistic society.

Contemporary workforce curriculum emerged in response to significant economic changes in the late 19th century. Rapid industrial growth and

sheer labor needs demanded new educational strategies. Economic production shifted from artisans and family-owned farms to large factories concentrated in urban areas. Processes for producing goods changed dramatically. On the factory floor, jobs were deskilled, tasks segmented, and workers distanced from the products of their labor. Workers who previously determined the pace of their daily labor had to adjust to corporate control. In the new industrial system, apprenticeship seemed increasingly irrelevant to workers' mastery of deskilled tasks and inadequate to train the number of workers industry needed.

Educators grappling with these changes found "manual training" a promising response. This applied curriculum championed a traditional work ethic and emphasized skills such as mechanical drawing, woodworking, tool use, or domestic science they could apply in varied industries. Books were cast aside in favor of hands-on activities. The innovative curriculum of a 19th-century Russian educator, Victor Della Vos, was particularly influential, including graded exercises that progressed in difficulty, and unlike apprenticeship, were not oriented to producing a particular product. The object was familiarizing youth with basic tools, shop processes, and common work materials. Although critics lamented that manual training might wrest precious moments from students' intellectual endeavors, advocates lauded its practical benefits, power to enrich academics, and potential to inculcate in youth the moral value of hard work.

Urgency to produce a skilled workforce gradually overshadowed manual training initiatives. In diverse efforts nationally, trade schools opened and offerings expanded in elementary, secondary, and high schools. Elementary students practiced applied skills and some adolescents attended trade school programs in which boys developed carpentry, plumbing, or electrical skills and girls learned sewing, millinery, and domestic science. In a shift Milwaukee manufacturers applauded, students learned skills relevant to local iron and steel manufacturing needs: pattern making, molding, tool use, practical mathematics, and mechanical drawing. Curriculum included lectures on the history of particular trades, visits to work settings, and practice using machinery and tools.

Educators' beliefs about race, class, and gender have shaped their curricular goals. Early manual

training advocates lauded hard work for "remedial" students, the orphaned poor, social delinquents, immigrants, and ethnic minorities. Similarly, administrators in 19th-century American Indian boarding schools perceived their pupils as "uncivilized" and used the curricular tools of uniform dress, English-only language use, agricultural education, and home economics to purge children's tribal customs and prompt assimilation to Euro-American ideals. Others envisioned African American freedmen as developing citizens who needed "realistic" and "practical" training in mechanics, farming, and blacksmithing to "advance" their social position after centuries of oppression. The attrition of White male students in the late 1800s spurred calls for "relevant curriculum" to keep these "potential drop-outs" settled at their school desks.

Vocational education history reflects fundamental philosophical differences concerning the role schools should play in shaping students' opportunities, eventual position in the social structure, and the appropriate curriculum for that mission. Some educators have favored tight links between schooling and work (for men, industry, and for women, the home), whereas others policed the borders of vocational space to preserve "authentic" work-centered curriculum. Some harnessed the socializing power of space to create workshops and housekeeping cottages to model future work settings. However, critics insisted that separate educational spaces and bifurcated curriculum undermined U.S. ideals of equal education. In their view, separate vocational spaces were not equal and U.S. citizens required *learning*, not *training*.

For example, reformers John Dewey and Jane Addams believed industrial efficiency damaged the human spirit. They championed a humanizing vocational curriculum to combat the tyranny of industrial mechanization. Dewey advocated vocational and academic integration, opposed tracking that segregated children and accentuated class divides, and urged educators to develop contextually specific learning activities to ensure dignity in human labor. Similarly, Addams sought to connect the seemingly fragmented tasks workers performed with broader production processes. Her curriculum included the unique educational space of her sprawling settlement community in Chicago, Hull House, in which residents worked collectively,

learned the historical development of such crafts as weaving, pottery making, and machinery, and participated in social reform. Approaching workers as humans first, Addams promoted a holistic curriculum of day care, nourishing food, and communal spaces. In sharp contrast, Frederick Winslow Taylor advocated “scientific management” to increase industrial and educational efficiency. Children were “raw material” from which educational managers could forge productive working adults. In Taylor’s model, humanistic curriculum irrelevant to students’ future work lives was deemed wasteful.

Funding has shaped vocational curriculum and standards significantly. The Smith-Hughes Act (1917), which mandated federal funding for vocational education, was instrumental in expanding its reach in schools and signaling worker preparation as a governmental priority. Among its mandates, the act required teachers to spend half of their instructional time on job preparation, thus providing more comprehensive training than single courses and hour blocks could provide previously. Additional acts in the 1920s and 1930s extended funds to home economics, agricultural education, and advertising courses. In the 1940s, acts funded rapid training for wartime production and vocational administration. Others supported career guidance to direct youth to “appropriate” vocations. More recently, rapid technological development and concern for U.S. citizens’ ability to compete in the global economy led to the Carl D. Perkins Vocational and Applied Technology Education Act (1990) and the School-to-Work Opportunities Act (1994), which promote integrating academic and applied curricula for context-specific learning.

The Smith-Hughes Act offers insight into how race, class, and gender have shaped vocational history. The act, which funded home economics but excluded clerical subjects, embedded in policy a curricular difference based on gender that reflected social anxieties about women’s increasing shift into paid employment. Home economics nourished women’s traditional roles as homemakers and prepared girls of color and immigrants for menial domestic service jobs. The act also posed different tracks for “concrete minded” and “abstract minded” students. Despite the popularity of commercial courses and business’s growing

need for clerical support, the act channeled funds to factory training rather than to white-collar office jobs.

Workforce curriculum has shifted in response to war, labor trends, and technological development. During the Great Depression (1930s), the government scrambled to address staggering unemployment issues through informal training programs for youth. Similarly, to meet wartime production needs (1940s), workers trained quickly for aviation, shipbuilding, and defense industries. As women’s social roles expanded throughout the 20th century, education expanded to include commercial education, interior decorating, instruction in child care, and courses in personal charm. The 1960s marked a shift to what historian Herbert Kliebard terms “vocationalization,” the philosophy that work preparation is the primary purpose of schooling. Contemporary vocational curriculum reflects these complex historical roots.

## VOICE

---

Curriculum studies at best rest on the twin pillars of enlightenment and liberation, knowledge and human freedom. A central requirement of curriculum in a democracy becomes the development of a distinct and singular voice in every student.

Teaching in a democracy is geared toward participation and engagement, and based, then, on a common faith: Every human being is of infinite and incalculable value, each an intellectual,

emotional, physical, spiritual, signifying, and creative universe.

Central to an education for citizenship, participation, engagement, and democracy—an education toward freedom—is developing in students and teachers alike the ability to think and speak for themselves. The core curriculum of a liberating education is this: We each have a mind of our own; we are all works-in-progress swimming toward an uncertain and indeterminate shore; we can each join with others in order to act on our own judgments and in our own freedom; human progress is always the result of thoughtful action. Students must learn to grapple—both now and in the future—with a question central to the spirit and heart of democracy, a question both simple and profound, straightforward and twisty: What’s your story? How will you find the voice to tell it fully and fairly?

All human life, of course, is in part a story of suffering and loss and pain. When that pain is preventable, the suffering undeserved, we resist, and in that resistance is another common-place in our human story. Sometimes our stories are ignored or diminished by others, sometimes we are seen through the heavy lenses of stereotypes and labels, our undeniable and indispensable three-dimensionality suffocated and diminished, our hopes handcuffed, and our possibilities flattened and policed. The development of a more powerful and compelling voice becomes even more essential.

It’s here that students draw upon their educations, on their own minds and their own spirits, to lift themselves up and beyond the negative and the controlling. What’s your story? Who are you in the world? What in the world are your chances and your choices?

Telling our stories, trusting our stories, listening carefully and empathically to the stories of others is part of the work of democracy. Everyone counts, and nobody counts more than anyone else. In a real democracy, the full development of each is the necessary condition for the full development of all. What’s your story? How is it like or unlike other stories? What are the next chapters going to be, and the chapters after that, and after that? No one knows for sure, for each person must write those next chapters—and even so, only partially, for every life is also a dance of the

dialectic, a sometimes difficult negotiation between chance and choice.

To be a good teacher in this context means above all to have an abiding faith in all students, to believe in the possibility that every person can create things and is capable of both individual and social transformation. Curriculum becomes a form of reinventing, re-creating, and rewriting, of finding voice, and this is a task that can be accomplished only by free subjects, never by inert objects. Curriculum, then, is a dialogical process in which everyone participates actively as equals—a turbulent, raucous, unpredictable, noisy, and participatory affair. The goal of dialogue in this context is critical thinking and action—voice and knowledge emerge from the continual interaction of reflection and action.

An emphasis on the needs and interests of the student is co-primary with faith in a kind of robust public that can be created in classrooms, as well as in the larger society. To be exclusively student-centered, to the extent that the needs of the group are ignored or erased, is to develop a kind of fatalistic narcissism; to honor the group while ignoring the needs of the individual is to destroy any real possibility of freedom. This is the meaning of community, the creation of places where people are held together because they are working along common lines in a common spirit with common aims. These are places of energy and excitement, unlike the sites of coercion and containment that are all-too-familiar in schools: The difference is motive, spirit, and atmosphere. These qualities are found when people move from being passive recipients to choosing themselves as authors, speakers, actors, builders, and makers within a social surround.

## VOUCHERS

---

Vouchers are certificates issued by the government to parents for the education of their children at a school of their choice. Vouchers function like admission tickets. Parents “shop” for a school, make their choice, and give the voucher to the school. Vouchers are designed to provide parents freedom to use all or part of the government funding set aside for their children’s education to send their children to the public or private school of their choice. In the field of curriculum studies, the topic of vouchers brings to light the various obstacles that many students face in gaining access to an education of quality. This topic also reveals how school funding methods and programs play a role in how students come to acquire the knowledge, skills, and values that they do in schooling.

The history of school vouchers dates back to 1792 when Thomas Paine proposed a voucher-like plan for England. In the United States, popular and legislative support, however, did not begin until the early 1950s, when states in the Southeast established tuition grants to respond to anticipated school desegregation. In a 1955 article, Milton Friedman, an eventual Nobel Prize-winning economist, proposed vouchers as free-market education, to separate government financing of schools from their administration.

Friedman’s view was that market-style competition for students would spur the development of schools that were better tailored to families’ needs and cost less than those run by inefficient public bureaucracies. Friedman argued that universal vouchers for students, from elementary through secondary schooling, would help launch an age of educational innovation and experimentation, increasing the options for students and parents and establishing the necessary conditions for promoting all sorts of positive outcomes.

Plans for a federally funded voucher program were developed by Christopher Jencks, a Harvard sociologist then working for the U.S. Office of Economic Opportunity. Congressional bills to fund such programs were introduced several times in the 1970s but these did not have broad support and were easily defeated. The voucher idea received more support after President Ronald Reagan endorsed it, and attempts to fund vouchers through

federal funding surfaced repeatedly in the 1980s. These legislative proposals, however, were perceived as elitist and were also defeated. In 1990, the first publicly financed voucher program began in Milwaukee, Wisconsin. Wisconsin lawmakers approved a plan for Milwaukee students to receive approximately \$3,000 each to attend nonsectarian private schools. This law was amended in 1995 to allow students to attend religious schools as well. It is this inclusion of religious schools first in the Milwaukee voucher plan and then in a similar plan in Cleveland, Ohio, that ignited the heated controversy and a series of lawsuits about vouchers. In 2002, the U.S. Supreme Court ruled the Cleveland program constitutional, paving the way for expansion to religious schools elsewhere.

Even though Congress and the U.S. Supreme Court have given their approval to vouchers, state courts and lawmakers remain cautious about these programs. Voucher programs exist in a small number of states. U.S. citizens remain divided about the voucher idea. Proponents argue that voucher systems promote free market competition among all types of schools, nonprofit or for profit, religious or secular. This competition among schools provides the necessary incentive for those schools to improve. The idea is that successful schools would attract students, and poor performing schools would be forced to reform or even close. Supporters further argue that voucher programs would help to equalize educational opportunities. The primary goal behind this idea is to localize accountability rather than relying on government systems of control to make school more equal in the United States.

Even with these many persuasive arguments for improving schools, most U.S. citizens continue to oppose vouchers, concerned that tax monies are redirected from public to private education, especially toward funding religious institutions. The National Education Association is one of the strongest critics of the voucher system. This organization and other public school teacher unions have spent millions of dollars litigating and lobbying against vouchers for concern that it could reduce funding and potentially cost public school teachers their jobs as students leave public schools for private schools. Critics also point out that families already have a choice within the public school system without vouchers.

Many objections have surfaced in the discussions about the potential effects of voucher programs on U.S. schooling, but most debates have focused on the First Amendment of the U.S. Constitution, which mandates the separation of church and state. Most private schools have sectarian affiliations; in particular, most of these schools are owned by the Catholic Church, an institution that supports voucher programs. Although this concern about the separation of church and state has merit, it has diverted public attention from the fact that voucher programs allow tax dollars to be used to subsidize high-status and high-price private schools. This subsidy can provide tuition relief for affluent parents, those who are able to afford these schools with the relatively small amounts of vouchers, and thus can become a means to finance tax relief for the wealthy. Thus, to many critics, voucher programs have the potential to be yet another way

of serving the interests of dominant cultural groups by reinforcing stratified structures in schooling and the outcomes of the curriculum.

## WALDORF SCHOOLS CURRICULUM

---

The Waldorf Schools curriculum is inspired by spiritual and moral discourses and is experienced as a union of sensory life and inner experience: a *spiritual science* approach. The Waldorf curriculum was developed by Rudolf Steiner (1861–1925), an Austrian scientist, philosopher, artist, social reformer, and educator, and was implemented at the Free Waldorf School (*Die Freie Waldorfschule*) for Boys and Girls, founded in Stuttgart, Germany, in 1919. Emil Molt, the owner of the Waldorf-Astoria cigarette factory, had invited Steiner to develop a school for his employees' children to educate in ways that might preclude catastrophes such as war. Thus, the impulse behind Waldorf education was and remains cultural and social renewal.

According to Steiner, instilling knowledge as abstract and separate from the whole dehumanizes society, and this knowledge, disconnected from values and feelings, is coldly destructive. Rather, a holistic and balanced development of intuitive, imaginative, and inspirational capacities—fully integrating knowledge, values, and feelings—would prepare children to contribute to social well-being and renewal. Steiner claimed that in educating the whole being, children would grow inwardly free, thus capable of resisting dogmatic and harmful ideologies.

This claim conflicts with a controversial aspect of Waldorf curriculum and the anthroposophical philosophy that undergirds it. Although the

curriculum and philosophy were so abhorrent to the National Socialist ideology that the Nazis banned the Anthroposophical Society in 1935 and forbade Waldorf schools to take on new students, current critics of Steiner's work claim an underlying racist/cultural hierarchical doctrine. Other critics object to Waldorf schools and anthroposophy as promoting occult beliefs. Both of these criticisms have been strongly refuted by the Association of Waldorf Schools.

However, a sense of helplessness in the face of cultural, economic, and political upheaval, similar to what Molt experienced in post-World War I Germany, has led many parents and teachers of today to seek a means of educating children toward social and cultural renewal. Frustrated by the government's role in education—using funding and testing mandates to coerce teachers and children into narrow and joyless experiences with the disciplines of knowledge—these educators and families note that the Waldorf curriculum reflects a different kind of consciousness. Steiner's articulation of spiritual science (*geisteswissenschaft: wissenschaft—knowledge and geist—spirit*)—is a way of seeing the world. And so, the work is based on not only *what* is seen but *how* it is seen—using a way of looking that combines “insiderness” and “outsiderness” for seeing the spirit in physical matter.

Waldorf teachers study anthroposophy, a view of the human being that guides them to teach with attentiveness and care, cultivating respect for the individuality of a child and the phases of childhood. Characterized by calm, patience, creativity, rhythms, and aesthetics, the Waldorf curriculum is

purposely designed in a holistic approach to teaching and learning with elements of science, the arts, religion, and human values working in concert to create wholesome work with storytelling a key-stone in developing the child's sense of order, cultivating self-discipline, and enjoying being one with the world. Social consciousness underlies the integrated curriculum of science, math, and social sciences as children learn to take part in the world.

The importance of community and humanity is reflected in the longevity of the classroom relationship. Children spend all of Grades 1 to 8 with the same classmates and the same teacher who teaches all the main academic subjects, but other teachers teach foreign languages, music, movement, handwork, and art. Narratives written by each of the teachers replace letter grades, and lessons are taught through stories, conversations, and rich experiences rather than through the use of textbooks. Students write and draw to document what they are experiencing in class in their "main lesson books" and these serve as textbooks.

Currently, there are more than 900 Waldorf schools in more than 80 countries, and some claim Waldorf education to be the fastest growing independent educational movement in the world. In 1968, the Association of Waldorf Schools of North America (AWSNA) was founded to support the growing number of North American Waldorf Schools.

## WAYS OF KNOWING

---

Curriculum studies focuses on identifying knowledge that is worthwhile. Ways of knowing are a

prerequisite concern that deals with how we can know what is worthwhile. How knowledge is obtained, attained, or acquired has long been the concern of a branch of philosophy called *epistemology*. Edmund Short shows how forms of curriculum inquiry are derived from and contingent on such ways of knowing in *Forms of Curriculum Inquiry*. Some of the most widely debated epistemological bases or ways of knowing include experience, authority, revelation, reason, empiricism, intuition, dialectic, dialogue and deliberation, critical inquiry, meditation, artistic engagement, embodiment, and indigenous forms of perceiving insight.

Experience creates a repertoire of cases, often informally, to be drawn on in future situations with similar attributes. John Dewey insisted that experience could be used to enhance the reconstruction of subsequent experience if it were subjected to careful reflection. Dewey differentiated between mere experience and *an experience*, conceiving the latter as providing increased meaning in the present by invoking connections between past endeavors and future possibilities.

Authority is placing faith in leaders, icons, traditions, literatures, oratory, mass media, propaganda, or other sources based on credentials, official licensure, or other aspects of reputation. Authoritative knowing can be influenced greatly by exercise of power, wherein persons accept authority because of fear of reprisal or oppression. This is a conflation of power with knowledge; yet it is all too prevalent.

Revelation is a form of authority that has played such a dramatic role in human history that it should receive separate treatment. The assumption is that we come to know the most important matters of life through communication, such as prayer or watchfulness, with a deity or deities.

Reason is adherence to accepted rules of intellectual discourse—ways of marshalling evidence and argument. In courts one is often admonished to consider what a reasonable person would do under specified conditions. Sometimes reason is defined as varied forms of accepted induction or deduction.

Empiricism combines reason, deduction, induction, and authority, sometimes called the hypothetical-deductive method or positivist science. It begins with a felt need in a dilemma, formulating

it as a question or problem, searching for evidence, formulating and studying hypotheses, analyzing intended and unintended consequences, and arriving at tentative conclusions that serve as pieces of a larger puzzle that enhances knowledge and induces additional research.

Intuition is a rapid or immediate apprehension of insight or understanding. With origins shrouded in mystery, some consider it fast, but others consider it derived from a connection with deeper dimensions of the universe that reveals truth. Mihaly Csikszentmihalyi has characterized a related form of apprehension as *flow*, whereas Donald Schön refers to *reflection-in-action*. Nel Noddings and Paul Shore have researched historical literatures of intuition as educational inquiry.

Dialectical reasoning traces at least to Plato's Socratic dialogues, wherein a thesis is argued and an antithesis counters it; through dialogue, a synthesis of the best of both is reached. The synthesis becomes a new thesis for which an antithesis is given, and a new synthesis emerges. Repeating the process creates and refines ideas. Georg Wilhelm Friedrich Hegel elaborated dialectic for historical phenomena, and Karl Marx developed it to characterize class struggle and revolution.

Dialogue and deliberation are variations on dialectics. Paulo Freire drew on Erich Fromm to call for dialogue between oppressed and oppressor. Joseph Schwab explicated eclectic deliberation or interaction between theoretic and practical knowledge, which may be traced to both Aristotle and Dewey.

Critical theory is inquiry that takes injustice as a given, and advocates knowing through a unity of inquiry and action, *praxis*, that seeks to rectify inequities of race, class, gender, place, culture, nationality, age, ability, religion, ethnicity, and language. Critical theory is derived from Marx, Herbert Marcuse, Jürgen Habermas, and others, and seeks to expose and overcome injustices. Critical race theory is a new variation that stems from legal studies and looks particularly at racial prejudices as contributors to injustice.

Meditation is a way of knowing exemplified in Eastern religious, philosophical, and cultural traditions. By losing one's self, insight is attained that enables connection with deeply embedded spirit, material, or energy of the universe, giving capacity to understand holistically.

Artistic engagement such as writing, painting, sculpting, playing or composing music, and dancing can be seen as forms of knowing in their own right—ones that integrate mind and body, thought and feeling, sensing and intuiting.

Embodied knowing pertains to the essence of many of these ways of knowing and is often associated with feminist thought and newer interpretations of pragmatism. Embodiment refers to an all-encompassing embracement of knowledge, via the mind and through apprehension by the whole body, and is absorbed in ways not unlike food or oxygen.

Indigenous ways of understanding may be captured in these categorizations; however, some scholars maintain that they incorporate still more epistemological bases, or knowing that is not epistemological. Norman Denzin, Yvonna Lincoln, and Tuhiwai Smith compile such perspectives and explore their relation to knowing.

Some scholars see ways of knowing as alternatives, and others favor eclectic uses or even dynamic syntheses of several. In any case, ways of knowing are central to curriculum studies. When examining curriculum research, theory, policy, or practice, it is important to be aware of the ways of knowing that support them.

## WHITE STUDIES RESEARCH, CRITICAL

---

Critical whiteness study in a multicultural educational context should delineate the various ways

such material effects shape cultural and institutional curricula and pedagogies and position individuals in relation to the power of White reason. Understanding these dynamics is central to the curricula of Black studies, Chicano studies, post-colonialism, and indigenous studies, not to mention educational reform movements in elementary, secondary, and higher education. This work is crucial to the field of curriculum studies for its scholarship as well as for curriculum design and development.

The history of the world's diverse peoples in general as well as minority groups in Western societies in particular has often been told from a White historiographical perspective. Such accounts erased the values, epistemologies, and belief systems that grounded the cultural practices of diverse peoples. Without such cultural grounding, students have often been unable to appreciate the manifestations of brilliance displayed by non-White cultural groups. Caught in the White interpretive filter, they were unable to make sense of diverse historical and contemporary cultural productions as anything other than proof of White historical success. The fact that one of the most important themes of the last half of the 20th century—the revolt of the “irrationals” against White historical domination—has not been presented as a salient part of the White (or non-White) story is revealing, a testimony to the continuing power of whiteness and its concurrent fragility.

Whatever the complexity of the concept, whiteness, at least one feature is discernible—whiteness cannot escape the materiality of its history, its effects on the everyday lives of those who fall outside its conceptual net as well as on White people themselves. As with any racial category, whiteness is a social construction in that it can be invented, lived, analyzed, modified, and discarded. Although Western reason is a crucial dynamic associated with whiteness during the last three centuries, many other social forces sometimes work to construct its meaning. Whiteness, thus, is not an unchanging, fixed, biological category impervious to its cultural, economic, political, and psychological context. There are many ways to be White because whiteness interacts with class, gender, and a range of other race-related and cultural dynamics. The ephemeral nature of whiteness as a social construction begins to reveal itself when we understand that

the Irish, Italians, and Jews have all been viewed as non-White in particular places at specific moments in history. Indeed, Europeans before the late 1600s did not use the label, Black, to refer to any race of people, Africans included. Only after the racialization of slavery by around 1680 did whiteness and blackness come to represent racial categories and the concept of a discrete White race begin to take shape. Such shifts in the nature and boundaries of whiteness continued into the 20th century. One of the reasons that whiteness became an object of analysis in the 1990s revolves around the profound shifts in the construction of whiteness, blackness, and other racial identities that took place in the last years of the 20th century. Indeed, critical multiculturalists understand that questions of whiteness permeate almost every major issue facing Westerners at the end of the 20th century from affirmative action and intelligence testing to the deterioration of public space. In this context, the study of whiteness becomes a central feature of any critical pedagogy or multicultural education for the 21st century.

### The Colonial Power of Whiteness

Although no one knows exactly what constitutes whiteness, we can historicize the concept and offer some general statements about the dynamics it signifies. Even this process is difficult, as whiteness as a sociohistorical construct is constantly shifting in light of new circumstances and changing interactions with various manifestations of power. With these qualifications in mind, a dominant impulse of whiteness took shape around the European Enlightenment's notion of rationality with its privileged construction of a transcendental White, male, rational subject who operated at the recesses of power while concurrently giving every indication that he escaped the confines of time and space. In this context, whiteness was naturalized as a universal entity that operated as more than a mere ethnic positionality emerging from a particular time, the late 17th and 18th centuries, and a particular space, Western Europe. Reason in this historical configuration is whitened and human nature itself is grounded upon this reasoning capacity. Lost in the defining process is the socially constructed nature of reason itself, not to mention its emergence as a signifier of whiteness. Thus, in

its rationalistic womb, whiteness begins to establish itself as a norm that represents an authoritative, delimited, and hierarchical mode of thought. In the emerging colonial contexts in which Whites would increasingly find themselves in the decades and centuries following the Enlightenment, the encounter with nonwhiteness would be framed in rationalistic terms—whiteness representing orderliness, rationality, and self-control and nonwhiteness as chaos, irrationality, violence, and the breakdown of self-regulation. Rationality emerged as the conceptual base around which civilization and savagery could be delineated.

This rationalistic modernist whiteness is shaped and confirmed by its close association with science. As a scientific construct, whiteness privileges mind over body, intellectual over experiential ways of knowing, mental abstractions over passion, bodily sensations, and tactile understanding. In the study of multicultural education, such epistemological tendencies take on dramatic importance. In educators' efforts to understand the forces that drive the curriculum and the purposes of Western education, modernist whiteness is a central player. The insight it provides into the social construction of schooling, intelligence, and the disciplines of psychology and educational psychology in general opens a gateway into White consciousness and its reactions to the world around it. Objectivity and masculinity as signs of stability and the highest expression of White achievement still work to construct everyday life and social relations at the end of the 20th century. Because such dynamics have been naturalized and universalized, whiteness assumes an invisible power unlike previous forms of domination in human history. Such an invisible power can be deployed by those individuals and groups who are able to identify themselves within the boundaries of reason and to project irrationality, sensuality, and spontaneity on to the other.

Thus, European ethnic groups such as the Irish in 19th-century industrializing United States were able to differentiate themselves from passionate ethnic groups who were supposedly unable to regulate their own emotional predispositions and gain a rational and objective view of the world. Such peoples—who were being colonized, exploited, enslaved, and eliminated by Europeans during their Enlightenment and post-Enlightenment eras—were

viewed as irrational and, thus, inferior in their status as human beings. As inferior beings, they had no claim to the same rights as Europeans—hence, White racism and colonialism were morally justified around the conflation of whiteness and reason. Before whiteness can place itself in the privileged seat of rationality and superiority, it would have to construct pervasive portraits of non-Whites, Africans in particular, as irrational, disorderly, and prone to uncivilized behavior. As rock of rationality in a sea of chaos and disorder, whiteness presented itself as a noncolored, nonblemished pure category. Even a mere drop of non-White blood was enough historically to relegate a person to the category of “colored.” Being White, thus, meant possessing the privilege of being uncontaminated by any other bloodline. A mixed-race child in this context has often been rejected by the White side of his or her heritage—the rhetorical construct of race purity demands that the mixed race individual be identified by allusion to the non-White group—for example, she's half-Latina or half-Chinese. Individuals are rarely half-White.

As Michel Foucault often argued, reason is a form of disciplinary power. Around Foucault's axiom, critical multiculturalists contend that reason can never be separated from power. Those without reason defined in the Western scientific way are excluded from power and are relegated to the position of unreasonable other. Whites in their racial purity understood the dictates of the “White Man's Burden” and became the beneficent teachers of the barbarians. To Western eyes, the contrast between White and non-White culture was stark: reason as opposed to ignorance, scientific knowledge instead of indigenous knowledge, philosophies of mind versus folk psychologies, religious truth in lieu of primitive superstition, and professional history as opposed to oral mythologies. Thus, rationality was inscribed in a variety of hierarchical relations between European colonizers and their colonies early on, and between Western multinationals and their “underdeveloped” markets in later days. Such power relations were erased by the White claim of cultural neutrality around the transhistorical norm of reason—in this construction, rationality was not assumed to be the intellectual commodity of any specific culture. Indeed, colonial hierarchies immersed in exploitation were justified

around the interplay of pure whiteness, impure nonwhiteness, and neutral reason.

Traditional colonialism was grounded on colonized people's deviation from the norm of rationality, thus making colonization a rational response to inequality. In the 20th century, this White norm of rationality was extended to the economic sphere where the philosophy of the free market and exchange values were universalized into signifiers of civilization. Once all the nations on earth are drawn into the White reason of the market economy, then all land can be subdivided into real estate, all human beings' worth can be monetarily calculated, values of abstract individualism and financial success can be embraced by every community in every country, and education can be reformulated around the cultivation of human capital. When these dynamics come to pass, the White millennium will have commenced—White power will have been consolidated around land and money. The Western ability to regulate diverse peoples through their inclusion in data banks filled with information about their credit histories, institutional affiliations, psychological "health," academic credentials, work experiences, and family backgrounds will reach unprecedented levels. The accomplishment of this ultimate global colonial task will mark the end of White history in the familiar end-of-history parlance. This does not mean that White supremacy ends, but that it has produced a hegemony so seamless that the need for further structural or ideological change becomes unnecessary. The science, reason, and technology of White culture will have achieved their inevitable triumph.

### **Positionality, Whiteness, and Critical Multiculturalism**

Individuals cannot separate where they stand in the web of reality from what they perceive. In contemporary critical social and pedagogical theory, this statement lays the foundation for the curriculum of "positionality." Positionality involves the notion that because our understanding of the world and ourselves is socially constructed, we must devote special attention to the differing ways individuals from diverse social backgrounds construct knowledge and make meaning. Critical multiculturalists, thus, are fervently concerned with White positionality in their attempt to understand

the forces, the power relations that give rise to race, class, and gender inequality. Those who claim the mantle of critical multiculturalism are concerned with the ways power has operated historically and contemporaneously to legitimate social and educational categories and hierarchical divisions. They are also interested in the ways individuals interact with representations of race, class, and gender dynamics in a variety of pedagogical spheres. Not content with simply cataloging such portrayals, critical multiculturalists take the next step of connecting representations to their material effects. Awareness of such effects are central in the effort to conceptually grasp the power-saturated, hegemonic process that grants analysts insight into the ways claims to resources are legitimated. At this point, critical multiculturalists are better equipped to describe the contemporary disparity in the distribution of symbolic/economic/pedagogical capital and the reasons it continues to escalate.

### **Research Issues and the Pedagogy of Whiteness**

How are students and other individuals to make sense of the assertion that whiteness is a social construction? How does such a concept inform the democratic goals of a critical multiculturalism? Such questions form the conceptual basis of our discussion of whiteness, our attempt to construct a curriculum and pedagogy of whiteness. To answer them in a manner that is helpful for Whites and other racial groups, it is important to focus on the nature of the social construction process. The discourses that shape whiteness are not unified and singular but diverse and contradictory. If one is looking for logical consistency from the social construction of whiteness, he or she is not going to find it. The discursive construction of whiteness, like the work of any power bloc, aligns and de-aligns itself around particular issues of race. For example, the discourse of White victimization that has emerged during the last two decades appears in response to particular historical moments such as the attempt to compensate for the oppression of non-Whites through preferential hiring and admissions policies. The future of such policies will help shape the discourses that will realign to structure whiteness in the 21st century. These discourses hold profound material

consequences for Western cultures because they fashion and refashion power relations between differing social groups. Any pedagogy of whiteness involves engaging students in a rigorous tracking of this construction process. Such an operation when informed by critical notions of social justice, community, and democracy allows individuals insights into the inner workings of racialization, identity formation, and the etymology of racism. Armed with such understandings, they gain the ability to challenge and rethink whiteness around issues of racism and privilege. In this context, questions about a White student's own identity begin to arise.

## WHOLE LANGUAGE/READING ISSUES

---

*Whole language* describes a method of, and philosophy regarding, the teaching of reading that is based on constructivist principles. Very popular in the 1980s and 1990s, whole language continues to play a part in discussions related to the best ways

to teach reading. The method emphasizes having children interact with reading, writing, and speaking through interconnected, meaningful activities rather than discrete subsets. This entry examines the theoretical underpinnings of whole language, some of the educational transformations its adherents favor, the controversy with phonics advocates, and its lasting influence. Insofar that decisions regarding whole language inform *what* is taught, *how* it is taught, and indeed that which *should* be taught, consideration of these issues are central to curriculum theory discussions.

Whole language is predicated on the belief that young readers learn best when engaged in making meaning when reading and expressing meaning when writing. In many ways, whole language represents a rejection of drill, charts, workbooks, textbooks, and other techniques that, when overdone, may discourage a beginning reader. Instead, whole language provides students with a print-rich environment, multiple opportunities to read and write, and exposure to authentic literature. Motivational aspects of literacy are emphasized, such as fostering a love of books and encouraging self-selection of level-appropriate reading materials.

Children in a whole language classroom learn about three cuing systems that regulate literacy development: *graphophonemic*, *semantic*, and *syntactic*. Children use the graphophonemic cuing system to find clues in the graphic input before them (i.e., using text to match letters to sounds), the semantic cuing system to make meaning from the context of what they read, and the syntactic cuing system to explore the principles and rules of the language. The three cuing systems overlap and allow the reader to guess appropriately. According to this approach, to learn to read, children need to understand the relevance of reading to their own lives, appreciate that they have something to contribute to the world of letters, and have access to reading and writing materials that will allow them to flourish. When these elements are in place, children learn to read and write without much direct instruction.

Whole language classrooms look different than traditional classrooms. Rather than standing in front of the classroom, teachers plan, coordinate, and facilitate a series of student-centered activities, where children engage in authentic reading experiences. Instead of more traditional focus on

grammar, spelling, and usage, whole language classrooms emphasize exposure to high-quality and culturally diverse children's literature, knowledge creation, the development of intrinsic motivation, and frequent reading. The whole language teacher reads *with* students, *to* students, and works *by* students throughout the day. Word recognition instruction, embedded phonics linked to literature being read, and writing mechanics are often presented in the form of *mini-lessons* that are presented when needed. Teachers integrate literacy skills into other areas of the curriculum, such as math, science, the arts, or social studies, so that students will not view literacy in isolation. Homogeneous and heterogeneous reading groups are used, with the membership in these groups being flexible and changing frequently. Whole language teachers emphasize the importance of knowledge creation, with students frequently asked to express their interpretations of text through art, dance, music, or writing, including the use of daily journal entries. Great importance is also placed upon students' reading independently, often through sustained silent reading (SSR) or drop everything and read (DEAR) times.

Although whole language continues to be very popular in the United States and other countries, the approach has generated criticism, especially among those who favor a traditional approach to instruction. Much of the criticism has focused around the teaching of phonics, which whole language opponents felt were not being given sufficient emphasis. Others suggested that teachers were abdicating their responsibilities, in essence expecting the students to learn on their own without formal instruction. When the reading performance of California 4th graders, as measured by the National Assessment of Educational Progress (NAEP), plunged, whole language was cited as a reason. Many parents advocated for a return to more traditional instruction. Many state legislatures, including California's, passed legislation that mandated explicit and systematic instruction in phonics. These efforts to return phonics to the classroom were supported by reports of the National Research Council's Commission on Preventing Reading Difficulties in Young Children and National Reading Panel, both of which rejected embedded phonics teaching in favor of a more explicit and systematic approach.

Proponents assert that critics of whole language instruction may have overlooked other factors that caused poor student performance, such as inadequate numbers of library books in low socioeconomic status neighborhoods and inadequate implementation of reading programs that used the process. These variables, as well as the general tension between the differing approaches to reading instruction have served as a centerpiece of the debates within the field of curriculum studies. Reports such as those of the National Reading Panel have been criticized for failing to include qualitative studies that indicated the merits of using a whole language approach. Currently, aspects of whole language, such as the movement's emphasis on quality literature, cultural diversity, and reading groups, have almost universal acceptance in the education community. Many schools, including those run by the New York City Department of Education, also recently have adopted *balanced literacy*, an integrative approach that incorporates many of the best features of whole language.

## WIDE-AWAKENESS

---

Nearly every practicing teacher has had experiences with students withdrawing from what is happening in the classroom. Some sink into a kind of lassitude; others, into a cloud of boredom. The

philosopher Martin Heidegger said that boredom was a response to a feeling of meaninglessness. When we recall the 19th-century poets' complaints of "ennui" or boredom in the face of an industrial world that felt alien to them, that offered nothing relevant to their interests or desires, we can understand what Henry David Thoreau would call the "somnolence" of those submerged in the ordinary.

The effort to arouse the inattentive may be described by the metaphor of awakening them. The phenomenologist Alfred Schutz used the term *wide-awakeness* to describe what he called the plane of consciousness of highest tension, this "originating in an attitude of full attention to life and its requirements." Rejecting mere passive taking in, the awakened person performs in a way demanded by the lived world as she or he perceives it. Conscious of lacks and deficiencies in that world, she or he may well exert energy to modify it. At once, there might be dialogue among those concerned with change, dialogue that makes audible diverse perspectives. Wide-awakeness requires translation of ideas. John Dewey, critical of fixities and "the crust of convention," infused his views of "doing" and "undergoing" in transactions with the environment with a requirement of reflective action. It would not be sufficient simply to interact with the human and physical world. The live creature must attend to what is happening as she or he moves through the problematic aspects of experience to intervals of resolution and on to often unexpected obstacles. Such obstacles demand deliberation as the individual goes on to decide whether to overcome what stands in the way or to bypass and avoid it, no matter how desirable the view on the other side. Wide-awakeness is necessary when alternatives are considered and choices are to be intelligently made. Committed as he was to the nurture of aesthetic experiences he called "extraordinary experiences," Dewey named the opposite "anaesthetic" perhaps another term for numb, or somnolent, a condition incompatible with an "attitude of full attention" or any effort to change the world.

Wide-awakeness is in some sense synonymous with Paulo Freire's concept of conscientization. Engaged in efforts to break through what he called "cultures of silence" or cultures where oppression deprived people of "voice," Freire stressed the development of critical literacy. He fought what he

called "banking education," a widespread tendency to "deposit" pieces of knowledge into the minds of passive students, old and young. Conscientization meant resistance to lack of awareness and lack of initiative in posing worthwhile questions.

Only through posing such questions could the oppressed name their worlds rather than simply accepting the interpretations or constructions made by their oppressors. Accepting in this fashion, the voiceless ones (peasants, say, excluded minorities, women in many parts of the world) were far too likely to internalize distorted, impotent images of themselves, agreeing in a peculiar way to be inferior beings at the pleasure of those with power—or thought to have power. Freire, probably more explicitly than others, identified what he called "humanization" with being highly conscious. His "pedagogy" became a process of humanization, of learning to pose the kinds of questions that might enable them to become critical and aware enough to make sense of their lived situations. Thought of in relational or dialogic terms, however, it was not enough to know or reflect or to "name." There had to be a transmutation into reflective practice to bring about change. And there had to be a coming together for the sake of cultural change.

Wide-awakeness in one form or other must infuse the democratic curriculum if it is to move toward participatory appreciation, action, and the inauguration of new beginnings.

## WOODSON, CARTER G.

---

Best known as the "father of Black history," Carter G. Woodson stands as one of the imminent

Black intellectual figures of the last two centuries. He integrated his interest in Black life with curriculum study. Woodson was a teacher, scholar, author, publisher, and organization administrator, and many contemporary scholars view Woodson's ideas as antecedents to Black studies and even multicultural education. Additionally, he was an acerbic and indefatigable critic of the curriculum offered African Americans in (segregated) schools.

Woodson was born December 9, 1875, to impoverished former slaves in New Canton, Buckingham County, Virginia. Attending elementary school only a few months per year, the mostly self-taught young man completed a 4-year high school curriculum in less than 2 years. He subsequently attended Berea College (Kentucky), became a high school principal, and completed the baccalaureate in literature. The University of Chicago graduate school would not recognize his Berea degree, forcing Woodson to earn another bachelor's degree from the University of Chicago in 1907. His subsequent University of Chicago master's thesis in 1908 examined French diplomatic relations with Germany in the 18th century. Moving on to Harvard, Woodson's 1912 doctoral dissertation on secession was entitled *The Disruption in Virginia*. He became the first African American of slave ancestry and only the second African American, after W. E. B. Du Bois, to receive the PhD from Harvard.

World travels took him to Europe, where he spent a full semester at the Sorbonne studying French; North Africa; and Asia where he worked for the U.S. Bureau of Insular Affairs as General Superintendent of Education in Manila, Philippine Islands. Fascinated with research, he sought employment in Washington, D.C., to be near the Library of Congress. His teaching résumé included courses in English, health, agriculture, U.S. history, French, and Spanish at local Washington, D.C., high schools.

Failing to get his dissertation published, he tired of academic politics and set out to organize a community of scholars committed to research Negro history. In 1915, Woodson, with associates George C. Hall, J. E. Stamps, W. B. Hartgrave, and A. L. Jackson, met at a downtown Chicago YMCA to establish the Association for the Study of Negro Life and History (ASNLH) later changed to the

Association for the Study of Afro-American Life and History (ASALH). Founded as a historical society to exclusively research Black America, the association's plan was that the organization be ideologically and politically independent. In 1916, the association established its first organ, a quarterly, the *Journal of Negro History*.

The school curriculum, especially history, soon became the focus of Woodson's attention. He evolved a philosophy about Black history. He wanted to free Black history from White intellectual bias, instead presenting Blacks as active participants in history. Additionally, he wanted both Black and White people to be exposed to the hidden contributions of Blacks. Negro history should be a part of the school curriculum. Finally, Woodson saw value in James Robinson's "new" history that asserted that history could serve social change.

Financing the ASNLH proved difficult because member dues were never sufficient. Woodson raised some funds from White corporate philanthropists; however, frequent disagreements and accusations of "radicalism" forced him into compromised situations and embarrassing requests that he declare his loyalty to U.S. capitalism. His passion became obsession as he worked tirelessly to protect and promote the ASNLH. Woodson never married or fathered children, and friends and supporters noted that Woodson took on assorted jobs and worked day and night for his association.

The spread of Pan-Africanism, Garveyism, and the emergent Renaissance cultural movement elevated the racial consciousness among African Americans. This climate provided support for "race men." Woodson founded Associated Publishers, Inc. in 1921 to produce books endorsed by the association. By 1925, the *Journal of Negro History* had published 10 monographs and 6,000 pages of articles. Woodson expanded his public presence by writing newspaper articles editorials and essays for Marcus Garvey's *Negro World*. His books and edited works around that time included *The History of the Negro Church*, *Negro Orators and Their Orations*, *The Mind of the Negro as Reflected in Letters Written During the Crisis 1800-1860*, and *The African Background Outlined*. In 1926, Woodson and his association made their indelible imprint on the United States

and the world as he (they) declared Negro History Week, now Black History Month.

The ASNLH became a cradle of curriculum activity. Woodson, as its leader, now focused his attention on schooling. He researched, theorized, and critiqued aspects of the school curriculum.

He noted the impracticality of the Black school curriculum. It was not designed or delivered to create productive, intellectually rounded, individuals. He likened it to the passing of information with no intention to educate. It was schooling without educating. He believed the Black psyche has been damaged contributing both to self-hate and intra-racial social class antagonisms. He challenged the motives of the White philanthropists who mostly favored the Hampton curriculum. This model of industrial education blocked liberal, classical, and progressive education for people of color. Even the Black teachers don't know what to teach, said Woodson. The architects and administrators of the curriculum were more interested in controlling rather than educating Blacks.

In 1933, he published his most celebrated work, *The Mis-Education of the Negro*, where he historicized and politicized the school curriculum offered Blacks. This penetrating work, written in very caustic language, critiqued the established school curriculum as grounded in racism and Eurocentric thought. Such education, he believed, could only result in the colonial subordination of African people in the United States. Several points were salient in this work.

Early in the book, Woodson illustrates subject by subject how Blacks have been either omitted or misrepresented in science, geography, and especially his beloved history. He insists people can't find their place in the world nor participate effectively without knowledge of their history. He argues further that certain subjects, for example, math, science, and language, serve as gatekeepers where Blacks are excluded from achieving. Even the medical school curriculum, notes Woodson, portrays Blacks as germ carriers.

The social consequences of Black education troubled Woodson greatly. The curriculum is not geared for the skill demands of the modern labor market. Black people, he feared, were ill-prepared for employment, advancement, and certainly the professions. As a consequence, Blacks were reduced to illicit hustling and the influences of charlatans.

The stereotypical Black preacher was a favorite target of Woodson.

Perhaps the most significant indictment of the curriculum for Woodson relates to civil society. He finds Black people crippled by their education. Their communities are torn. They are eliminated from participation and, most importantly, leadership in social and political life. Without good education, Blacks can never exercise self-determination and emancipation. Woodson's assessment of the deleterious effect of existing schooling on the Black psyche held that educated Blacks would dissociate themselves from the masses of their people and could never achieve unity and racial advancement with this brand of education.

His other works include *Negro Makers of History*, *African Myths*, *The Story of the Negro Retold*, and *African Heroes and Heroines*. His books for schoolchildren were often accompanied by study guides, chapter questions, and recommended projects.

Interestingly, Woodson's life and work chronologically overlapped that of "progressive" educators including the Progressive Education Association, and their "radical" outcasts, the social reconstructionists, yet there is no evidence that either influenced the other. The racial divide in critical curriculum discourses remains nearly a century later.

Woodson was honored with the prestigious Spingarn Medal from the National Association for the Advancement of Colored People along with several honorary degrees. The U.S. Postal Service honored him with a memorial stamp in February 1984. Woodson died of a heart attack on April 3, 1950, in Washington, D.C.

## WORKSHOP WAY OF LEARNING

---

Workshops for educators have been an integral part of professional development and inservice education. The workshop format is loosely interpreted as an opportunity or a requirement for schoolteachers or leaders to develop new knowledge, skill, or disposition designed to enhance curriculum. The idea of workshop, as a way of learning, was refined by Earl C. Kelley in the 1940s and elaborated in his book, *The Workshop Way of Learning*.

Kelley's workshop ideas were influenced by the educational theory of John Dewey and by practices initiated by Ralph W. Tyler in the Eight Year Study of the 1930s and early 1940s. Origins also bear some resemblance to statewide curriculum reform efforts led by Hollis Caswell in Virginia and in Florida, spanning from the 1920s to the 1940s, and to the work of L. Thomas Hopkins in Colorado, California, and New York in the 1920s and 1930s, and in the 1960s and 1970s in Maine and other states, as well as in post-World War II Germany.

Origins in the Eight Year Study are particularly significant. Teachers from experimental secondary schools across the United States seeking to develop progressive education practices were given summer opportunities to refresh their efforts at several different colleges and universities, such as Sarah Lawrence. Some of these efforts consisted of making curricular and instructional materials that they took back to their schools to implement in subsequent years. The most experimental schools, those that practiced more radical interpretations of Dewey's philosophy, however, used the workshop opportunity not primarily to make materials, but to develop themselves. Instead of asking what was worthwhile for their students, they asked what was worthwhile for themselves. Thus, they pursued a

kind of curriculum of teacher renewal that engaged them in increased self-understanding and consideration of what kinds of contributions they could make to society through their lives as educators. Rather than taking a product back to apply to students in their classrooms, they took a workshop method of asking: What is worthwhile? By sharing this orientation to learning with students, the educational experience took on new dimensions of meaning.

Kelley developed such an approach during the 1940s at Wayne State University in Detroit. *The Workshop Way of Learning* explicates and illustrates the approach. Beginning with a statement of principles and purposes, Kelley situates the workshop in a practical interpretation of Deweyan theory that includes appreciation of individual worth, the primacy of personal interests and concerns as a starting place for workshop learning, the central place of human relations and cooperation, and the assumption that the best learning begets more learning. Teacher participants in Kelley's workshops were encouraged to take responsibility for their own learning, to evaluate and revise it on a continuous basis. A central assumption was that the participants would take that learning back to their classrooms as primarily a method that could be used with students and secondarily in the form of materials that could facilitate such a method or *way of learning*. Throughout the book, Kelley presents the following: procedures for getting workshops started, the development of interest groups among participants, applicable resources, examples of application in general sessions, strategies for reducing barriers among participants, modes of evaluation, illustrations of outcomes, discussion of unsolved problems, examples of a brief workshop, and concluding discussion of dilemmas and possibilities for future applications.

Although the *workshop* for educators has continued to be used, great variation exists in practices and in philosophy behind them. Sometimes one finds applications that are relatively consistent with those advocated by Kelley. More often that which is labeled *workshop* is criticized as a one-shot attempt to indoctrinate participants in a particular approach that will benefit a cause (often state or corporate) that is far removed from the immediate concerns and interests of participants that Kelley advocated and that could be derived from Dewey's

philosophy. Nevertheless, Kelley's model remains for those who want to develop workshops that provide long-term personal and social learning experiences for educators as forms of inservice education or professional development.

## WORLD COUNCIL FOR CURRICULUM AND INSTRUCTION

---

The World Council for Curriculum and Instruction (WCCI) is a transnational educational organization committed in its mission to advancing the achievement of a just and peaceful world community and promoting person-to-person, professional relationships. It is a nongovernmental organization of the United Nations in consultative status with a consultant to the United Nations Educational, Scientific, and Cultural Organization (UNESCO). The preamble of the WCCI constitution challenges educators in the world community to ensure that education contributes to the promotion of equity, peace, and universal realization of human rights, developing a comprehensive sense of respect of self, others, and the environment.

The history of the WCCI originates with the Association for Supervision and Curriculum Development (ASCD), its 1950 Committee on International Understanding, and its 1966 Commission on Cooperation in Education. Alice Miel is credited as the founder of WCCI and the first to suggest a world conference. Louise Berman, another well-known curriculum scholar, was also essential to the founding of WCCI.

ASCD has long been distinguished by its attraction of researchers in curriculum studies and teaching at odds with more traditional approaches. In

1970, when ASCD held its first world conference at Asilomar in Pacific Grove, California, more than half of the 300 participants represented countries other than the United States. Endorsing more diverse and international approaches, participants determined to form an international organization, designated the WCCI. In 1974, WCCI officially separated from ASCD. WCCI sponsors conferences, exchanges, and global projects, and publishes related papers (see Table 1).

**Table 1** WCCI World Conferences

<i>Date</i>	<i>Place</i>
1974 September	Keele, England
1977 September	Istanbul, Turkey
1980 December	Tagaytay, Philippines
1983 July	Edmonton, Canada
1986 August	Hiroshima, Japan
1989 September	Noordwijkerhout, The Netherlands
1992 August	Cairo, Egypt
1995 December	Amritsar, India
1998 July	Bangkok, Thailand
2001 September	Madrid, Spain
2004 July	Wollongong, Australia
2006 August	Manila, Philippines
2008 September	Antalya, Turkey

*Note:* Originally triennial, conferences moved to every other year in 2004.

Leaders of WCCI include Louise Berman, Virginia Cawagas, Gulab Chaurasia, Jaime Diaz, Maxine Dunfee, Mina Fayez, Larry Hufford, Estela Matriano, Norman V. Overly, Alice Miel, Frithjof Oertel, Betty Reardon, Piyush Swami, and Swee-Hin Toh, who have been role models in curriculum development as well as in peace education.

## WORTH, WHAT KNOWLEDGE IS OF

---

In his 1861 book, *Education: Intellectual, Moral, and Physical*, Herbert Spencer coined the phrase, “What knowledge is of most worth?” He used it as a chapter title, upon which he developed his Social Darwinist response that argued for knowledge that fosters human self-preservation as the knowledge of most worth. Although Lester Frank Ward, John Dewey, and others who followed to create curriculum studies disagreed profoundly with Spencer’s doctrine of *survival of the fittest* relative to human society and education, his emphasis on knowledge that is most worthwhile persisted as a salient issue of the curriculum field throughout both its curriculum development era (circa 1900 to 1970) and its curriculum studies era (1970 to present).

The question posed by Spencer captured an interest within the long history of speculation by philosophers, theologians, and social theorists about what kind of society is best and how human beings should be educated to develop it. As curriculum theorists developed the question from the early years of the 20th century on, it became modified and refined. Criticism focused on roots of curriculum in colonization, that is, dominant social groups tend to guide curriculum decisions and subaltern or colonized voices are not heard. Such criticism ranged from subaltern voices, such

as W. E. B. Du Bois, Carter G. Woodson, and Paulo Freire to those accepted within the curriculum field, such as George Counts, Harold Rugg, Michael Apple, William Pinar, Henry Giroux, Jean Anyon, Linda McNeil, Michelle Fine, Lois Weis, Joe Kincheloe, William Watkins, and Ming Fang He. From varied critiques derived from such sources, a new question emerged to temper the original Spencerian question: Who benefits and who does not? Moreover, the emphasis on *most* was diminished, remaking the question, “What knowledge is worthwhile?” This diminished the one-best-answer criticized in favor of increased diversity and pluralism. Further, the idea of *knowledge* itself was perceived by many as a limiting factor in curriculum studies. Thus, emphasis on other dimensions of human and societal growth through education have made the question more robust over the years. Today, it becomes much more inclusive: What is worth knowing, needing, experiencing, doing, being, becoming, overcoming, sharing, contributing, and more?

In essence, the question, stated in its most streamlined form today is, *What is worthwhile?* It is often argued that this question is the unifying concern of curriculum studies. It can be seen in all of the attempts to summarize or capture the state of the curriculum field, such as in synoptic curriculum texts, at various junctures throughout curriculum history.

## ZIRBES, LAURA

---

The contributions of Laura Zirbes (1884–1967) to the field of curriculum lie in three areas: (1) as a consummate progressive teacher and teacher educator; (2) as an early advocate of classroom-based, teacher-initiated research; and (3) as a steadfast leader in professional organizations dedicated to the improvement of educational practice. In 1948, the National Women’s Press Club recognized her achievements in education with an award as “Woman of the Year,” presented to her by President Harry Truman. With more than 200 publications, hundreds of speeches and workshops for inservice educators, and a career of more than 60 years teaching at all levels of schooling, she advocated an elementary curriculum that recognized the developmental needs of the child, the centrality of experience in learning, the integration of content areas, and the role of creativity for achieving human potential.

Zirbes began teaching 4th grade in Cleveland, Ohio, in 1903. Immediately, she challenged lock-step, recitation methods in favor of approaches that considered children as individuals with unique backgrounds and needs. An early article on experimentation in her own classroom led to a position at the Lincoln School at Teachers College, Columbia University, where she also earned bachelor’s, master’s, and PhD degrees. In 1928, she relocated to The Ohio State University where she taught until her retirement in 1954. In her later years, she

continued teaching at many universities and offering workshops and institutes for teachers.

Her position at the Lincoln School as investigator in reading enabled her to explore the impact of individualized instructional methods on reading and to challenge the use of basal readers and standardized tests. In these efforts, Zirbes demonstrated an inquiring mind, open to questioning and observing teaching practices. She also participated in the development of the school’s principles of child-centeredness, an integration of subject areas, and a valuing of the arts.

At Ohio State, she expanded these views in summer demonstration schools and in work within a local public school and in a private building she financed herself; these efforts led to the establishment of the elementary school within the College of Education’s University School. As director of research in the University School, she championed a pragmatic progressivism designed to encourage teachers’ thinking as they put progressive theories into practice. For more than 35 years, teachers and students preparing to teach visited the university school and participated in intensive workshops to see progressive practices in action and to observe how teachers collaborated around key principles.

Zirbes participated actively in the work of the school’s elementary teachers through informal influence that stressed developmentalism, the role of firsthand experience in learning, the integration of subject areas, the centrality of democratic values, and the need for cooperation rather than competition in children’s work. She also recognized

that structure was still necessary to foster healthy learning. In so doing, Zirbes avoided either-or thinking, an approach that enabled the application of these practices in a wide variety of public school settings. Her work thus presaged movements in elementary curriculum during the late 1960s and the early 1970s based on the British Infant School model and the whole language movement of the 1990s.

Zirbes's commitments to teacher education spanned both preservice and inservice programs. She developed the elementary teacher education program at Ohio State to include community service, field experiences in the local public schools, seminar and workshop pedagogies, and the use of emerging technologies in the classroom. She also founded Walhalla House, a pre-kindergarten and kindergarten demonstration setting and educational laboratory. Here, too, preservice teachers could observe the development of relationships with parents and the importance of teachers' social responsibilities in the school community.

Zirbes extended this involvement in the professional growth of teachers through her work in various professional organizations across her long career, for example, in the Progressive Education Association, the Association for Supervision and Curriculum Development, and the Association for Childhood Education International. Along with hundreds of speeches and workshops, these contexts provided her with opportunities to champion the need for a developmental perspective to guide teaching, the importance of teacher growth if children were to grow in their presence, and a pragmatic approach to helping teachers apply progressive principles in their classrooms.

For Zirbes, writing occurred to share her views with teachers. More than 200 books and articles appeared in venues for practitioners and as resources

for classroom teachers. However, her 1959 text, *Spurs to Creative Teaching*, served as a capstone to her thinking, honed over many decades. Using an innovative style to engage the reader with the text, she stressed that teachers must always move forward in their thinking and that creative teaching exemplified democratic values and led to educational fulfillment. Here, she built on her work in developmental curriculum to articulate a view of teaching which demanded constant growth.

Zirbes's influence on curriculum arose from her work as a teacher of teachers. She modeled her beliefs, stood firm for her values, demonstrated practices in school settings, articulated a middle-of-the-road progressivism, and thereby educated generations of teachers who, in turn, moved the mainstream elementary curriculum from drill and recitation to child-centered, developmentally appropriate approaches to learning.

## Fundamental Curriculum Questions

---

---

### LIST OF FUNDAMENTAL QUESTIONS ON CURRICULUM MAKING USED AS THE BASIS FOR THE PREPARATION OF THE GENERAL STATEMENT: *THE FOUNDATIONS OF CURRICULUM MAKING*

---

The *26th Yearbook of the National Society for the Study of Education (NSSE), The Foundations and Technique of Curriculum-Construction*, has taken on legendary dimensions and is best known in curriculum studies for the second portion of the publication, Part II, which contains a composite 18-page statement, *The Foundations of Curriculum Making*, with 58 individual planks composed by the committee of 12 authors: William C. Bagley, Franklin Bobbitt, Frederick G. Bonser, W. W. Charters, George S. Counts, Stuart A. Curtis, Ernest Horn, Charles H. Judd, Frederick J. Kelly, William H. Kilpatrick, Harold Rugg, and George Works. As a prelude to the preparation of their composite statement, committee members staged five large-group roundtable meetings, lasting from 1 to 5 days, and scheduled various other occasions where smaller groups met to discuss a series of topics and questions that served as the nucleus for the composite, general statement.

In an effort to display the dynamic, timeless quality of this publication, to suggest that the field of curriculum studies remains linked to its curriculum design and development past, and to underscore the *26th Yearbook's* profound ability to generate

thoughtful conversation and insight, two curriculum scholars—Timothy Leonard and Peter M. Hilton—were invited to address, from a contemporary perspective, the list of fundamental questions on curriculum making.

Craig Kridel

#### 1. What Period of Life Does Schooling Primarily Contemplate as Its End?

This first question was meant to address the relationship of compulsory education to the workplace. At the time of the *26th Yearbook*, there was as yet no federal law regulating the employment of children, and the compulsory education age-range varied from state to state. Conditions were such that approximately half the children in the United States were not in school by the time they reached the age of 16. Writers of the yearbook debated whether or not curricula should be designed to prepare students for work or to provide real experiences that were significant in their own right and not just as preparation for work and adult living.

The vast changes in contemporary life since the 1920s demand that this question be looked at anew. Children are in school longer than they were then; jobs come in and out of existence more quickly and require skills that cannot reasonably be taught in 8 or 12 years of school. Community colleges, proprietary schools, and union-sponsored trade schools routinely enroll students in their

30s and 40s. Universities sponsor programs for adults in lifelong learning institutes that primarily promote learning in the humanities for adults of any age. If one includes all the educational organizations offering curricula, the answer must be that schooling does not, these days, contemplate any period of life as its end.

In the early 1800s, Free School Societies in New York, Baltimore, Philadelphia, and other cities established schools for the children of working people in basic literacy and arithmetic. The tax-supported common school movement, as it grew through the 19th century continued to aim at producing a literate and civil workforce. This aim continued to be central to public schooling into the 1920s and on into the present day. Many important voices throughout the 20th century decried this narrow utilitarian view of public education, but by and large, Americans were content with their schools as long as young people were prepared for good jobs and behaved with a modicum of civility. Yet the popularity of the contemporary adult education programs in the humanities throughout the United States challenges us to think about this question in a very different light. Is there an age, one might ask, at which education in the humanities is not of paramount importance?

Elliot Eisner highlights two characteristics of humanistic studies that support an understanding of this question. The humanities, he says, shed light on what it means to be a human being and sharpen one's ability to make good judgments. Eisner shows how insight into patterns of human feeling flow out of appreciation of and work in art, music, and dance; how studies of literature and drama enhance one's sense of self and awareness of others; and how studies of history and even of science from the perspective of its historical development enable us to realize the underlying distinction between nature and culture. In addition to work like Eisner's, there is a growing body of research in neurobiology and anthropology that shows deep connections between education in the arts and emotional and cognitive development.

It is clear, then, that schooling that aims narrowly at job preparation and a modicum of civility is not adequate to the needs of our time. Humanities education, as broadly conceived by the authors of the recently published *107th Yearbook* of the NSSE, should be a prominent focus of all school

curricula. When schooling works effectively to achieve humanities education, there is no period of life at which it should end. Whether such a notion of schooling should be supported by taxes is a matter for voters to decide.

## 2. How Can the Curriculum Prepare for Effective Participation in Adult Life?

The prevalent assumption in public discourse on education in the United States is that preschool is preparation for kindergarten, kindergarten is preparation for first grade, elementary school is preparation for high school, high school is preparation for college, and college is preparation for a job. Also, at each stage, the work of the student is understood as a preparation for a test. The assumption has always been problematic in the field of curriculum studies.

One way to get beneath the surface of this problem is to consider the basic principles of pragmatism as enunciated by Charles Sanders Peirce that the meaning of things is to be found in their consequences. Peirce held that it is impossible for humans to have ideas about things unless they can conceive of the sensible effects of those things. If Peirce was correct, curricula are best understood in terms of their effects, their practical results. On this view, to consider curricula solely in terms of preparing for adult life would be to distort their meaning. On the other hand, to consider curricula only in terms of the present moment is to rob it of its complexity. Curricula resonate with effects; some intended, some anticipated, some hoped for, some neglected, some unnoticed. The resonance of a curriculum—that is, its intended and unintended effects—requires careful attention from curriculum designers.

A dramatic example of this comes from outside the United States. On March 24, 1980, the entire country of Nicaragua became one large school. Nicaragua had just successfully driven out the dictator, Anastasio Somoza Debayle, and the Sandanistas understood their first task to be to making the people of Nicaragua literate. Students from high schools and colleges in and around Managua, the capitol city, were recruited to become brigadistas, or literacy volunteers. They were trained to become teachers of reading, writing, and basic mathematics, and from March until

September they went into the countryside to teach. In 1979, a census had revealed that over 50% of Nicaraguans were illiterate, and in rural areas, the rate was 75%.

The approach that the brigadistas took was designed to establish dialogue with illiterate Nicaraguans. Photographs were shown and served as the basis for dialogue about specific political and economic problems that they faced. These photographs were set in a reading primer, and each photograph, along with discussion questions, was the basis of dialogue about the specific situation that this or that group of Nicaraguans faced. In the primer, each photograph and discussion was followed by a lesson in constructing sentences related to the discussion. The mathematics book was titled *Mathematics and Economic Reconstruction: One Single Operation*. The instruction was dialogical, deliberately political, and revolutionary following the work of Paulo Freire. Learning was practiced as a shared responsibility among learners and teachers.

The resonance of this curriculum was impressive. From March to September of 1980, 406,000 illiterate Nicaraguans were taught basic reading and writing skills by this massive army of young people. The testimony of many of the young people who participated in this campaign demonstrated a growth in awareness on their part of the social and political situation in the country, and the illiteracy rate was reduced from 30% to 6% in the cities and from 75% to 21% in rural areas. The meaning of this curriculum was situated in its cultural and social context. There are many other examples, but any curriculum with such resonance prepares learners for effective participation in adult life.

The Nicaraguan Literacy Campaign did not focus on preparation for adult life. Rather, it engaged young people and adults in a shared venture in literacy and democracy. The experiment demonstrates the possibility of creating resonant curriculum that is both preparation for and participation in adult life.

### 3. Are Curriculum-Makers of the Schools Obligated to Formulate a Point of View Concerning the Merits or Deficiencies of American Civilization?

To understand this question, it is helpful to consider two important terms: *cultural hegemony* and

*reification*. Cultural hegemony refers to a process whereby the dominant view of a culture renders alternative views of the culture irrelevant or meaningless. Reification refers to the process of rendering abstractions into fixed physical objects. Normally, curriculum designs, as syntheses of culture, unquestioningly reflect the hegemonic point of view. By not explicitly formulating their point of view, these designers reify their curricula. The hegemonic view of curriculum design at the time of the *26th Yearbook* was the technical rationalism exemplified by the work of Henry Harap, the most widely used curriculum technician of the period. The yearbook describes several exceptions to this such as the curricula of the Lincoln School at the Teachers College of Columbia University and the Francis Parker School in Chicago, yet the work of Franklin Bobbitt, W. W. Charters, David Snedden, and Henry Harap dominated the field.

Some of the editors of the yearbook decried this conservative dominance of the 1920s and advocated that curriculum workers involve textbook publishers in a process that would engage the public in developing a more critical stance towards society. Harold Rugg went further, and published a 14-volume textbook series in social studies grounded on these principles. In the 1930s, George Counts raised a critical question in *Dare the Schools Build a New Social Order?* and Carter Woodson condemned the Manichaeic division of U.S. culture between Whites and Blacks in his book, *The Mis-Education of the Negro*, demanding a curriculum that credited Black Americans with the significant contributions they had made to U.S. life.

A significant curriculum project based on a well-formulated point of view about the merits and deficiencies of U.S. culture is to be found in the Progressive Education Association's Eight Year Study. The study advocated participation of individual schools, teachers, and students in the development of the curriculum as a method of evaluation of the surrounding society and culture.

Curriculum theorists such as Michael Apple and Landon Beyer have, since the 1980s, offered a more radical critique of society that decries the hegemony of unbridled capitalism in the culture and in the curriculum of the schools. The work of Patricia Holland and Noreen Garman is grounded in trusting the human imagination in both traditional and

critical curriculum practice and serves as a useful complement to these theorists.

Curriculum workers ordinarily develop curriculum without articulating a point of view about the merits and deficiencies of U.S. culture. When such a point of view is well articulated and deeply held, curriculum becomes far more dynamic, interactive, and meaningful.

#### 4. Should the School Be Regarded as a Conscious Agency for Social Improvement?

One way to approach this question is to examine the text that has served as a paradigm for curriculum development since the late 1940s—that is, the Tyler Rationale. Ralph Tyler published *Basic Principles of Curriculum and Instruction* in 1949 while he was a professor at the University of Chicago. It can be argued that this slim volume has been the most significant text in the field of curriculum ever since.

Tyler held that in order to develop a proper curriculum four questions need to be answered: (1) What are the school's educational purposes? (2) What educational experiences will likely attain these purposes? (3) How can the educational experiences be properly organized? (4) How can the curriculum be evaluated? Curriculum theorists such as George Posner and Landon Beyer have pointed out that the Tyler Rationale reduces the first question about educational purposes to a procedural and technical matter, whereas they view the question of educational purposes as definitive. In stating this, Posner, Beyer, and others hold that curriculum designers, before they proceed with their design, must determine whose interests are to be served by the curriculum. In this way, these critical theorists stake their claim that curriculum should be regarded as a conscious agency for social improvement.

George Counts in the 1930s and 1940s and Theodore Brameld in the 1950s and 1960s promoted similar views dedicated to the idea that the school must be an agent of social change, forming a school of thought called *social reconstructionism*. Criticism of these views center on two questions: Can schools be instruments of social change? And ought schools be instruments of social change?

Whether or not it is possible for schools to be instruments of social change is a question that has

puzzled educators and social thinkers for years. After all, adults are responsible for social change, and children get socialized into the adult world, not the other way around. Brameld's response to this question was that the curriculum should be owned and controlled by teachers, parents, and students, and no one else. His confidence in the wisdom and power of the common person was unbounded, and some say utopian.

Whether or not the schools ought to be instruments of social change is another matter. Historically, schools were created to pass on the culture to the next generation and have served a conservative function in the culture, which begs the question of what is to be conserved in a fundamentally democratic society. The answer of many contemporary curriculum thinkers such as George Wood, Deborah Meier, TheodoreSizer, and the authors of *Facing History and Ourselves* is clear. Surely it is not the function of the U.S. schools to conserve authoritarianism and mindless conformity. Rather, it seems clear that schools ought to conserve the common sense of Thomas Paine, the courage of George Washington, the sense of justice of Martin Luther King, the temperateness of Abraham Lincoln's Second Inaugural address, and the persistence of Susan B. Anthony. A curriculum that conserves these elements would also be a curriculum that serves as an instrument of social change.

#### 5. How Shall the Content of the Curriculum Be Conceived and Stated?

In their irreplaceable book *Curriculum Books: The First Hundred Years*, William Schubert and his colleagues discuss the construction of the *26th Yearbook* and the struggle of the editorial board to arrive at a consensus statement about the content of the curriculum in the United States. Schubert and his colleagues provide a useful framework for understanding why such a consensus was not achieved, and how one might look coherently at this question. Schubert said that there were three distinct visions of curriculum content among the members of the editorial board: (1) the intellectual traditionalists, such as William Bagley; (2) the social behaviorists, such as Franklin Bobbitt; and (3) the experientialists, such as William Heard Kilpatrick. It is fitting to

look at the yearbook in this way, for it was not intended to be a set of principles to be blindly followed, but as Harold Rugg said in the introduction to the second part of the yearbook, *The Foundations of Curriculum Making*, the common statement was to be a “bone of contention to be chewed upon, and not a platform to stand upon” (p. 8).

Intellectual traditionalists, who followed what was called a subject-organized curriculum, viewed the curriculum as a set of separate subjects derived from the cultural past. These professionals were not pedants. They were alert to the dangers of attempting to cover too much material and insisting upon rote memorization of facts. They stressed, for example, in the teaching of botany in a manner that demonstrated how botanists work. They understood that separate subjects could be correlated so that students would be provided opportunities to grasp connections among the subjects they studied. There is little evidence that their ideas about memorization or the correlation of subjects were put into immediate practice. However, in the 1930s, the Eight Year Study experimented with correlating subjects with a broad fields approach to curriculum grounded in problem solving. Similarly, in the 1960s, the social science curriculum *Man: A Course of Study* blended the biological and social sciences into one curriculum, and J. Lloyd Trump experimented with flexible modular scheduling, an approach to innovative block scheduling for the purpose of interdisciplinary studies, an approach that continues to this day. A contemporary approach to curriculum integration may be found in the work of James Beane.

The experientialists, who were called child centered, viewed curriculum from the point of view of the students’ experience of school. These thinkers followed John Dewey’s idea that all education begins with the experience and the interests of the child and attempted to build curriculum as a process of guiding students in the reconstruction of their experience towards responsible participation in adult and democratic life. The debate between the intellectual traditionalists and the experientialists has been renewed in each decade since the 1920s, most recently in a public conversation on the Internet between the historian Diane Ravitch and the progressive educator Debbie Meier. An

attempt to heal this gap was introduced in the 1960s by Arthur King and John Brownell in which they conceived the curriculum as a community of discourse among and between the disciplines of knowledge. Professional scientists, mathematicians, artists, musicians, linguists, and writers participated in this community of discourse along with administrators, teachers, parents, and students. All participants, they said, can learn and contribute in their own way to the ongoing inquiry and discourse.

The social behaviorists viewed curriculum primarily as an instrument of administration and a technique for the control of student learning. They tended to draw their ideas of curriculum content from surveys about the content of adult life at work, at home, and in leisure time. Based on these surveys, social behaviorists built sets of goals and objectives, or more recently standards and benchmarks, for the curriculum. This view conceived curriculum work primarily as a technical process that was less concerned with school subjects or student experience than it was with measurable outcomes. Of the three visions, the social behaviorist view has dominated curriculum practice over the years, especially in the recent period of the standards movement. The challenge for curriculum studies today is to keep the other two visions in play so the field can maintain itself, as Rugg described, a bone of contention to be chewed upon.

## 6. What Is the Place and Function of Subject Matter in the Educative Process?

There are, in general, three functions of subject matter in the process of education, which, working together, serve the interests both of individual students and the society. First, subject matter provides children and youth with a store of common knowledge and wisdom. Common knowledge includes the geographic, historical, civic, and literary understandings that provide young persons with a sense of identification with a civilizational past and a cultural present—a sense of citizenship in one’s nation and the global community.

Second, subject matter provides a depth of understanding of oneself in the world, a depth of understanding of what it means to be a human person within the story of the universe, the story of

life, the story of human history, human knowledge, and the symbols that enable this story to keep moving forward. The physical and life sciences provide this depth of understanding, along with the symbol systems of mathematics, language arts, and the languages of other peoples.

Third, subject matter stimulates the imagination, the inquiring consciousness, and the critical mind that enables students to imagine the real possibilities in the present moment, to critically examine the civilizational past and the cultural present, to make music, to dance, and engage in the arts. Music, art, and physical education are the primary subjects that deal with imaginal learning, and yet the imagination feeds the other two areas of the curriculum as well, and all three of these areas are fundamentally and dynamically connected.

Curriculum theorists all hold the importance of subject matter in the curriculum. There are, however, many disagreements within the field of curriculum studies about the role and function of subject matter. For example, Philip Phenix described the role of subject matter in curriculum emphasizing the integration of the subjects into the whole person and with an openness to ultimate meaning. Other curriculum inquirers foreground one or another of the three functions.

With regard to the first function of subject matter, E. D. Hirsch puts it in the foreground, as the core of common knowledge. Hirsch holds that the critical thinking implicit in the third role of subject matter requires basic understandings of the facts contained in those subjects.

Maria Montessori also foregrounds the first function of subject matter by emphasizing the story of the universe, the story of life, and the needs of humans for food, clothing, shelter, security, transportation, and spirituality as the basis of the education of children from age six to age nine. This, she said, would provide children with a sense of their role in the ongoing story of life.

The second function, depth of understanding of self in the world was a basic aim of the curriculum reform movement of the 1950s and 1960s. Jerome Bruner taught that children can participate in the community of inquirers that make up school subjects, and as they grow in age, they should follow a spiral curriculum that draws them deeper and deeper into the inquiry. Joseph Schwab, whose work is echoed in many respects by the work of

TheodoreSizer and the Coalition of Essential Schools, held that it is preferable to know a few subjects in depth than many subjects superficially. Schwab understood the teacher as the bridge between the formal curriculum and the curriculum as students engage with it. Using the arts of the eclectic, teachers choose from the fund of their knowledge of subject matter and their knowledge of the practice of teaching to apply subject matter to the concrete situation of the classroom.

A useful place to go to understand the foregrounding of imagination and critical intelligence is the Discipline Based Arts Education program (DBAE) sponsored by the J. Paul Getty Foundation, which integrates the visual, musical and performing arts through studio and performance work as well as a study of history, aesthetics, and criticism. This approach to subject matter is to be found also in the work of Elliot Eisner, Maxine Greene, and William Pinar.

### **7. What Portion of Education Should Be Classified as “General” and What Portion as “Specialized” or “Vocational” or Purely “Optional”?**

Benedict de Spinoza was a lens grinder, a craftsman, an artist, and one of the greatest European philosophers of the 17th century. It is that ideal synthesis of a good solid trade and a highly intellectual education that is sought in answering this question. Rarely does formal education achieve such integration, for the relationship between general education and vocational education has never reached a settled understanding in the United States. Traditional and progressive curriculum thinkers, though they disagree on its nature, tend to consider a good general education as an adequate preparation for work in the world, or for further professional or vocational studies. In 1917, a deep divide between general and vocational education was struck by the Smith-Hughes Act, which set vocational education and general education on entirely different tracks.

Charles Prosser, one of the foremost advocates of Smith-Hughes, believed, along with Edward Thorndike, that all learning was specific and segregated from other learning. Transfer of training, in their view, did not exist. In vocational education, therefore, Prosser advocated a curriculum in which

the activities of students mimicked the activities of workers in specific fields as closely as possible. Smith-Hughes established vocational and technical education districts to be separate from regular school districts, virtually separating vocational and general education in the United States. In some ways the junior college became an extension of this system of schooling. Smith-Hughes mandated that if a student received federal funds for vocational education, 50% of his or her class time would be devoted directly to the training he or she needed for the job. The other 50% would be devoted to support courses and general education.

W. W. Charters said that the curricula for vocational education should be developed through functional or job analysis. Such analysis included personality profiles for specific trades. Carpenters, for instance, according to Charters, did not need to be as accurate or as rapid as machinists, but carpentry required more neatness than machinists' work. All the activities of workers in fields as varied as potters and poultry workers were to be analyzed, and these activities were to be the basis for implementing Smith-Hughes.

The curriculum reform movement of the 1950s and 1960s generally ignored dealing with this separation. In the 1980s, the cognitive psychologist Lauren Resnick claimed that paying attention to the differences between school learning and learning in the workplace could support the development of a curriculum that reflects the complexity of contemporary life. School learning, she said, focuses on individual work and individual achievement, whereas learning in the workplace demands shared understandings and communications to achieve shared purposes. School work, she said, emphasizes pure thought, whereas workplaces are structured by the requirements of manipulating the available tools and symbols necessary to accomplish concrete tasks. Resnick, noting that schools to help students become competent out-of-school learners, advised that the building of curricula that pay attention to the kinds of thinking required outside school could simultaneously serve the interests of general and vocational education.

Resnick became a member of the board of the Secretary of Labor's Commission on Achieving Necessary Skills (SCANS), which in 1991, published a report that did not address the structural

issues of vocational education, but did look seriously at the conceptual divide between vocational and general education curricula. SCANS developed a conception of a general education that would better prepare students for the workforce. SCANS, however, maintained the method of Job Analysis initiated by Charters, and from the perspective of curriculum traditionalists, treated general education as little more than instrumental of vocational education. From the standpoint of progressives, SCANS gives over too much of the curriculum to the values and direction of the business community. The question of the relationship between general and vocational education remains, in practice, unanswered.

### 8. Is the Curriculum to Be Made in Advance?

The question of whether the curriculum should be made in advance has played a central role in the field of curriculum studies. It also seems to be a preoccupation of teachers in schools. School administrators, however, tend to think the question is settled: Of course, the curriculum is to be made in advance, how else could instruction be delivered? The separation of curriculum from teaching that is instantiated in that kind of thinking and in the practices of school district offices, state legislatures, and the U.S. Office of Education must be addressed to answer this question.

Between the census of 1890 and the census of 1910 the majority of the U.S. population moved from the countryside to the city. During that period, ferment about what was to be taught in schools heightened. Immigration, industrialization, and urbanization were bound to influence questions of what students in elementary and secondary schools need to know and how that knowledge would influence them in adult life. In sum, the question of Herbert Spencer, "What knowledge is of most worth?" reformulated in 1993 by Michael Apple as "Whose knowledge is of most worth?" had to be answered.

The National Education Association (NEA) played a major role in effecting an answer to Spencer's question. In 1876, the NEA, largely under the influence of William Torrey Harris, prepared the report, "A Course of Study from Primary School to University," and in 1893, the NEA sponsored The Committee of Ten, which was given the

task of establishing a secondary school curriculum. Both of these efforts focused primarily on the subject areas that students would need for adult life, or for college or university.

In 1918, Franklin Bobbitt published *The Curriculum*, the first book totally dedicated to the making of a school curriculum. He and his associate W. W. Charters, for all practical purposes, created the field of curriculum development as an activity of technical design. Their principles were taken from the field of industrial management as developed by Frederick Winslow Taylor, and prescribed a process of activity analysis for the development of educational objectives, and activities. Thus, the curriculum developer, in a process separated in time and place from the classroom, would design educational objectives and activities based on the observed activities of competent adults in science, industry, family life, and labor. The teacher's task then was to apply the curriculum through instruction.

Progressive educators during the growing industrial period disagreed with both the NEA's subject matter emphasis and the technical-rational approach of Bobbitt and Charters. Harold Rugg and Anne Schumacher rejected both for their relative inattention to the individual child. John Dewey rejected them for their inattention to what he would call the educational situation—that is the meeting in a moment or range of moments between a prepared and inquiring teacher and a classroom of children, each with his or her own personal history and experience. Dewey's work demonstrated that the dispute between the progressives and the others was about authority. The academic traditionalists and the technical rationalists both believed in the authority of the distant expert, whereas Dewey thought authority in the classroom resided in the student's natural need to reconstruct his or her experience in an actual situation with an actual knowledgeable, inquiring, responsible adult called a teacher.

Currently, there are traditionalists, such as Diane Ravitch, and followers of Mortimer Adler's *Paideia Proposal* or E. D. Hirsch's *Core Knowledge* who uphold the belief in a preplanned subject matter-based curriculum. Others, such as Grant Wiggins, Roger and David Johnson, Robert Marzano, and the U.S. Office of Education more closely follow the line of thought begun by Bobbitt

and Charters. Progressives such as Deborah Meier, Michael Apple, Elliot Eisner, and Parker Palmer have inherited the progressive view, emphasizing the notion of situated learning.

In the new century, the technical approach of Marzano and others dominates curriculum practice. Some districts have closed down their curriculum departments, but maintain strong commitments to the development and selection of standardized tests that are aligned with national, state, and local standards. Thus, curriculum development is, in practice, largely a matter of selecting textbooks that support improvement in standardized test scores. This practice creates tensions between teachers and school administrators, for it is clear that, in practice, the knowledge of the experts behind the standards, the tests, and the textbooks is held to be of greater worth than the practical insights of teachers in actual educational situations.

### **9. To What Extent Is the Organization of the Subject Matter a Matter of Pupil-Thinking and Construction of, or Planning by, the Professional Curriculum Maker as a Result of Experimentation?**

Recent debates about U.S. education have tended to exaggerate the differences among the three visions of curriculum described in the answer to question five. Diane Ravitch and E. D. Hirsch, for example, portray a stark divide between progressives such as John Dewey and perennialists such as William Bagley. Similarly, some progressives treat social efficiency curricularists as if they did not care about general education. Though there were deep differences among these persons' visions of curriculum, it must be remembered that Dewey and Boyd Bode affirmed the value of traditional subject matter, Bagley honored the experiences of children as inherent to the educative process, and Franklin Bobbitt, particularly later in life, was committed to general and humanistic education.

When one examines the *26th Yearbook*, therefore, one finds a general commitment among the editors to an ongoing process of comprehensive curriculum study on the part of curriculum committees. These committees would include subject matter specialists, teachers, and other specialists who would be willing and able to pay careful

attention to the experiences of students as they work their way through the curriculum. In that sense, the editors advocated experimentation, or what later became known as action research or more currently, site-based staff development.

The recent winner-take-all debates about the public school have not served the curriculum field well, and the result has been the reduction of curriculum to a business-efficiency model that focuses almost entirely on technical matters and the development of standardized tests in the name of science. If the curriculum field were to reestablish the dialectic among the three visions of curriculum described in the yearbook, the place of the teacher in the process of curriculum making would be enlarged, the participation of university faculty and subject area specialists would become essential, and the notion of science utilized in the federal legislation No Child Left Behind would expand to include history, the humanities, ethnographic research, and philosophical analysis.

The conversation required to restore and renew curriculum practice would accept the reality of opposed principles, opposed ideas, and opposed practices as normal. Then, through experimentation and conversation, curriculum committees could compare principles, practices, and results not merely to show one to be better than another, but to find the benefits and deficits of each and all. Trust in the experience, the good will, and the intelligence of all those engaged in the work has the potential to realize the notion of Harold Rugg that opposing curriculum ideas provide opportunity for discourse and discussion. What is at stake here is the very idea that curriculum is always grounded in the kinds of choices educators make as they attempt to answer the unanswerable question: "What knowledge is of most worth?"

### **10. From the Point of View of the Educator, When Has "Learning" Taken Place?**

Question 10 asks about assessment and evaluation, terms about which there is some lack of clarity. Assessment generally is taken to mean the process of obtaining, interpreting, and documenting information about student learning. So assessment includes pretesting, posttesting, observing student behavior, interviewing teachers and students, and reviewing teachers' assignments

and student work including exhibitions, portfolios, presentations, tests, and written work, sometimes with the guidance of a scoring rubric. Evaluation, on the other hand, is making the judgment about what students have learned based upon the evidence gathered in the assessment process.

Assessment and evaluation take place on two levels: evaluation of what students have learned and the evaluation of the curriculum and instruction that has guided their learning. The way one goes about evaluating students or curriculum depends upon the purpose of the evaluation and the use to which the information and the judgment shall be put. In 1967, Michael Scriven made an important distinction between formative and summative evaluation. The purpose of formative evaluation is to improve current practices and processes in classrooms and schools. The purpose of summative evaluation is to make judgments about the worth of the results of those practices and processes in order to improve student learning and the curriculum for the future.

Scriven made another significant contribution, which has been elaborated by Robert Stake through what they have called goal-free or responsive evaluation. In this approach, the evaluator does not attend to the goals and purposes of the curriculum, but uses qualitative methods such as close observations, in-depth interviews, and grounded theory in order to discern the kinds of learning that occur quite apart from the intentions of the curriculum makers.

Elliot Eisner has described a form of evaluation called educational connoisseurship. This practice is not unlike Scriven's goal-free evaluation and has many similarities with Joseph Schwab's arts of the eclectic. The educational connoisseur observes the student, the classroom, or the curriculum as a drama critic might observe a play. Noting the context of the object being evaluated, the connoisseur draws upon all the elements in the setting and in the wider world, and makes a holistic judgment of their worth.

Judgments about whether learning has taken place, then, are never definitive. Rather, they are inferences based on data that have been gathered in a variety of ways from a variety of sources for the purpose of improving curricula and student learning. For this reason, using scores on standardized

tests to judge the knowledge of a student or the worth of a curriculum must be complemented with multiple sources of data including data from student work on assignments and the professional judgment of classroom teachers so that these pieces of information can be used to improve student learning and curricula.

### 11. To What Extent Should Traits Be Learned in Their “Natural” Setting?

This question is best understood in the context of the curriculum movement called social efficiency. A trait is a habitual way of relating to one’s world and to other persons. It is what some educators today call a disposition. David Snedden and his student Charles Prosser held that a person’s character is a sum total of his or her traits. On this basis, Franklin Bobbitt and W. W. Charters developed the method of activity or job analysis, which observed and analyzed the behavior of adults and developed curricula that would as closely as possible have students mimic those behaviors in school. Philip Jackson has called this approach to curriculum mimetic teaching. Mimetic teaching has manifested itself over the years in various curricula such as vocational education, education for democracy, life-adjustment education, and character education.

The belief that a person’s character is the sum total of his or her traits is peculiarly behaviorist in origin and contrasts with the traditionalists’ understanding of character as intellectual and spiritual, as well as the progressives’ understanding of character as active, dynamic, and inquiring. Mimetic curricula, then, are very useful, but when used to the exclusion of traditional and progressive curricula they are inadequate to the task of preparing the young to live in an increasingly complex world. Moreover, the tendency of social efficiency educators to exclude some studies, such as Latin or philosophy or literature from the curriculum on the grounds that they are not efficient or useful is short-sighted.

There are at least three alternative approaches to curriculum for character education that differ from and may complement the learning of traits from their natural setting. The first of these is generally called character education such as *The Children’s Morality Code* published in 1917 by William

Hutchins. This approach provided rules for conduct for children aimed at developing habits of self-control, good hygiene, good workmanship, truth telling, and teamwork. Prominent in this approach is the contemporary program *Character Counts*, which is based on what are called six pillars of character: trustworthiness, respect, responsibility, fairness, caring, and citizenship.

The second approach focuses on decision making and the facing of moral dilemmas. Merrill Harmin, Louis Rath, and Sydney Simon pioneered this approach in the 1960s with their work on values clarification, which used exercises to help students clarify their values and change their behavior. In a slightly different way, Lawrence Kohlberg worked on a developmental approach to moral reasoning by presenting children with moral dilemmas to think through and solve.

A third approach has been explored by Kevin Ryan and Karen Bohlin and concerns itself with virtue ethics and what may be called communities of character. Drawing on a range of resources, this approach aims at developing shared visions, values, and virtues in a school community.

The education of character has long been of central importance in the U.S. curriculum and remains a major challenge to contemporary education. The narrow focus on selecting educational activities that match desirable traits to their natural settings as captured from adult life cannot meet that challenge. When curriculum workers, including teachers, devise simulations; tell stories; practice improvisations; study and engage students in discussions of art, science, mathematics, music, and literature; and implement service learning projects, they communicate to students that the moral life is central to human living. To achieve remembrance of that seriousness in students’ later awareness and practice is a central goal of curriculum.

### 12. To What Degree Should the Curriculum Provide for Individual Differences?

All curriculum practitioners affirm the need to provide for individual differences among learners. The way they understand this question and act in relation to it, however, varies broadly. A useful way of understanding these differences is to examine different stances curricularists take

toward the content of the curriculum, the processes of implementing the curriculum especially in terms of teaching practices, and the kinds of results sought through this content and these processes.

In the 1970s, Benjamin Bloom developed *Mastery Learning* as an individualized approach through which individual students would master what the schools wanted them to know and be able to do at their own pace and through methods that were most appropriate to their needs and styles of learning. Later, systematic designers of instruction such as Walter Dick and Lou Carey, focused their attention on the purely technical aspects of curriculum, such as the analysis of behavioral outcomes, the needs of individual learners, instructional delivery options, and setting up online instructional systems for distance learning. Whether intended or not, these approaches, in practice seemed to be reduced to the achievement of behavioral objectives as measured by standardized tests.

The cognitivist David Ausubel took a less linear approach. Focusing on verbal learning, Ausubel set out a two-dimensional chart that ranged from rote learning to meaningful learning on the one hand, and from discovery learning to receptive learning on the other. In general, he thought, learning followed a path through discovery and rote learning to meaningful and receptive learning, and the task of curriculum and instruction was to guide students along this path by using what he called *advance organizers*. An advance organizer is a technique that enables students to connect what they already know with what is mapped out before them as what they will soon come to know. This approach, which in some sense is a reprise of the work of the 19th-century German philosopher Johann Friedrich Herbart, has assumed many forms over the years and has been used widely and elaborated more fully particularly in the work of Carol Ann Tomlinson and those who promote differentiated instruction.

While combining elements of behaviorist and cognitivist approaches, differentiated instruction begins as a response to the needs students have in common such as the need for safety and belonging and to those characteristics, which differentiate one student from another, such as their learning styles and emotional makeup. Like those other

approaches, differentiated instruction adapts teaching methods and pacing to individual students and utilizes continuous diagnostic and formative assessment. But more than those approaches, differentiated instruction pays attention to the students' search for meaning in their lives, to the right balance between providing safety and challenge, to the need for collaborative learning, and to the differences inherent in gender, race, language, class, socioeconomic status, and culture among them.

Each of these approaches pays considerable attention to individual differences in terms of educational procedures and results, yet they pay insufficient attention to the content of the curriculum—that is, to the following questions: What knowledge is of most worth? And whose knowledge is of most worth? Traditional thinkers such as E. D. Hirsch and Chester Finn and progressive thinkers such as TheodoreSizer and Michael Apple have spent much time and energy devoted to those questions, yet the disagreements among these groups point to a need for rapprochement between all parties—that is, traditionalists, progressives, curricularists, and instructional technicians. To what degree should the curriculum provide for individual differences, is still, after all these years, a live question.

The U.S. government has offered an answer to this question through No Child Left Behind's Response to Intervention (RTI). This accountability approach mandates what are called scientifically proven strategies to address individual needs. The widely publicized lament over RTI on the part of teachers and the general public would indicate the question is, indeed, still open.

### 13. To What Degree Is the Concept of “Minimal Essentials” to Be Used in Curriculum Construction?

At the turn of the 20th century there was much ferment between teachers and curriculum experts, most of whom were specialists in content areas. As a result, the National Education Association formed a Committee on the Economy of Time (COET). This committee was established to explore wastes of time and potential savings of time in the school curriculum. Through analyzing and quantifying the activities of adults, the

committee attempted to pare down the elementary school curriculum to include only those learnings that were of most social utility. This was a watershed moment in the history of the U.S. elementary school curriculum in that curriculum was no longer left in the hands of subject matter specialists, but was to be constructed by processes educators considered to be scientific.

From 1911 to 1915, COET published four yearbooks for the NSSE concerning what the editors called the minimum essentials. The authors believed that the curriculum from elementary school through college could be reduced from 16 to 14 years. The *14th Yearbook* is a classic in the tradition of social efficiency in curriculum studies. The report claimed that the greatest waste in those 16 years was to be found in the elementary school curriculum, which they wanted to reduce from 8 to 6 years. The essential knowledge, habits, ideals, and attitudes for individual and social needs, they said, could be learned in that amount of time.

The authors and editors settled on a two-stage process for defining these minimum essentials. In the first stage, curricularists needed to decide which subjects and which parts of subjects were both comprehensible and socially useful for the students at any given level. In the second stage, they developed criteria for excluding curriculum material. To exclude material, its social utility needed to be weighed against the time and effort it took for a majority of students to learn it. When the committee finished its work, the members realized that their results were tentative and incomplete. So the question of the place of minimum essentials was still alive at the time of the *26th Yearbook*.

In the 1940s, it was widely thought that Ralph Tyler had resolved the question by including the needs of society, the needs of learners, and the demands of subject area specialists as the basis for curriculum construction. But actually, what Tyler did was bring to light that the rationale for minimum essentials was not so much science as it was philosophy. In the 1950s, academic traditionalists such as Arthur Bestor and progressive thinkers such as Jerome Bruner attempted to reemphasize the importance of subject matter and the disciplines of knowledge in curriculum building. In the late 1960s and 1970s, a more child-centered approach was championed by educators such as Herbert Kohl and John Holt.

The standards movement, which officially began in 1983, has, ironically, much in common with the advocates of minimum essentials and the work of both Bestor and Bruner. Yet this movement led to the No Child Left Behind Act (NCLB). The assessment approach mandated by NCLB has vitiated any connection the standards movement may have had with the likes of Bestor and Bruner. An almost universal rejection by teachers of current state and local testing practices has garnered responses from curricularists such as Linda McNeil who advocate the collaboration of students and teachers in the cocreation of curriculum.

One promising development in this debate has been a growth in scholarly interest in teacher education. One such effort began in 1991 with the Holmes Partnership, which is a consortium of 80 schools and colleges of education committed to academic improvement of teacher education programs. The Holmes Partnership schools affirm the need for high academic standards in colleges of education, which, in addition to requiring broad and rich liberal education, require teacher candidates to achieve a degree in an academic discipline in addition to their professional education degree. Teachers with such strong academic backgrounds ought to be trusted to develop curriculum at the schools in which they teach. Progressive educator Deborah Meier affirms such an approach to curriculum improvement, and it has been proven effective in the education miracle that has occurred in Finland, where colleges of education are the most competitive colleges in the universities.

#### 14. What Should Be the Form and Organization of the Curriculum?

The form and organization of the curriculum is in every case a matter of choice, the product of a decision. The curriculum is in essence a selection of culture and politics, and the selection that is made depends upon the cultural and political interests of the curriculum designers.

Herbert Kliebard has suggested that there are three major tendencies among curriculum designers that may be expressed in terms of three metaphors: (1) the metaphor of production, (2) the metaphor of growth, and (3) the metaphor of travel.

The metaphor of production has dominated curriculum development since the 1920s beginning

with the scientific rationalist approach of Franklin Bobbitt, W. W. Charters, and David Snedden and continued through the 20th century culminating in *No Child Left Behind*. The form of curricula developed under this metaphor is fundamentally industrial. Curriculum designers delineate the specifications of the results they want to achieve and state them in terms of goals and objectives or standards and benchmarks. They then set out to design and organize materials and procedures in such a way that teachers can deliver instruction in a manner and pace that will produce the desired results. These results are often expressed in terms of grades, grade-point averages, or standardized test scores. The approach is so common that in ordinary conversation one hears graduates of particular schools referred to as products of those schools. The major interest here is the control of the process and the product of the curriculum.

The metaphor of growth is at least as ancient as civilization itself, for it represents the inevitable resistance to the rules and regulations imposed by civilization. It was the basis of the educational classic *Emile*, of Jean-Jacques Rousseau. Johann Heinrich Pestalozzi provided a major impetus to this way of thinking about curriculum by focusing on the inner capacities of the individual child and permitting children to grow first as they observe and interact with the world around them and only later through language, mathematics, and other subjects that would broaden their horizons into personal and social maturity. Friedrich Froebel and, later, Maria Montessori expanded upon Pestalozzi's work through developing elaborate sets of materials and placing them in what Montessori called a prepared environment in which the child naturally grew with the support of a carefully observant, tender, and relatively unobtrusive teacher. Contemporary followers of Jean Piaget, called *constructivists*, have also inherited this tradition. Eleanor Duckworth and Eileen Knight have made significant curricular contributions in science and mathematics from this perspective. The major interest in this case is the growth of the individual child.

The metaphor of travel has much in common with the metaphor of growth, but it moves beyond the growth of the individual child to the broadening of the child's horizons into the world of public responsibility. The content of the curriculum—that is, reading, writing, mathematics, science,

social studies, fine arts, and humanities—are taken as seriously as they are under the earlier two metaphors, but all these studies are understood in terms of how they may be used to engage and in some cases, transform the world. Perhaps the best exemplar of the travel metaphor was Boyd Bode. A progressive, Bode insisted on grounding curriculum on social and public philosophy and understood the subject matters of the curriculum as instruments to inspire students to engage in democracy as a way of life. The major interest served by the metaphor of travel is the emancipation of society, and some curricularists such as George Counts and, later, Michael Apple understood the school primarily as a force to achieve justice in U.S. society and culture. The philosopher Maxine Greene emphasized the notion that the transformation of the individual consciousness of students leads directly to the transformation of society.

Because curricula are grounded in choice, curriculum studies is a normative field of study, and requires scholars to understand the deep connection among the goals chosen, the standards embraced, the materials and textbooks selected, the teaching practices encouraged, and the methods of evaluation adopted. Once scholars grasp those connections, they are required to engage in ethical dialogue about whose interests are being served by each curricular approach. In such a way, curriculum scholars can clarify who is and who ought to carry the burdens of justice in our society.

### 15. What, if any, Use Shall Be Made of the Spontaneous Interests of Children?

The authors of this question were struggling to come up with a way to synthesize their disparate views of curriculum making. This was quite a challenge, for as editors of the *26th Yearbook*, they represented a wide range of opinion precisely about this question. William Bagley, whose views have been called essentialist, held firmly to the primacy of school subjects, especially language, mathematics and science, and had a low regard for the project method advocated by another of the editors, William Heard Kilpatrick. There was a similar conflict between the views of Franklin Bobbitt, whose activity analysis functioned as a method for the reproduction of the contemporary society, and those of George Counts, who was

moving from the child-centered views of some progressive educators to a theory that the school should be an instrument of social reconstruction. In a joint statement, these four and the eight other members of the yearbook's editorial board dealt with their differences with generosity and civility, yet they could not come up with a synthesis concerning the place of spontaneous student interests and the making of a curriculum.

Ten years before the NSSE *26th Yearbook*, in his book *Democracy and Education*, John Dewey defined interest as being enraptured by some object and to be alert and totally attentive. Dewey thought that when students pursue their interests, they develop the required discipline that enables them to reconstruct their original concern into new and vital knowledge, a very reconstruction of experience. Whether or not the interests of the children, conceived in such a profound sense, can serve as the mainspring of curriculum making remains an open question to this day. Clearly, Dewey himself had a nuanced view of school subjects and did not reduce curriculum to a working through of children's interests.

Maxine Greene has recast the question of the curriculum and the child's interest by talking about a student's re-creating the materials of the curriculum in terms of his or her own consciousness. This manner of conceiving curriculum takes for granted that the materials of the curriculum are to be selected as a synthesis of culture and that the task of the student is to transcend the narrowness of his or her own personal world and empathically engage with and be transformed by the curriculum, thereby enriching herself, the curriculum, and the culture. The curriculum maker's task then becomes one of selecting and framing school subjects, materials, and practices in such a way that moves children beyond superficial motivation to vital engagement with the public world in which they are participants.

### 16. For the Determination of What Types of Materials Should the Curriculum-Maker Analyze the Activities in Which Adults Actually Engage?

The term *material* in this question included textbooks, audio-visual aids, and whatever learning situations a curriculum maker might choose for

students. The editors of the yearbook were concerned that people thought learning to be merely the ability to repeat back correct words, phrases, or formulas without genuine understanding of their meaning. To move beyond mere memorization was important to every member of the board, for they understood learning as any change in students' ability to manage their conduct in an increasingly advantageous manner. In fact, they coined the term *advantageous learning* to make this point. It was agreed, therefore, that lifelike learning experiences needed to be discovered and chosen for incorporation into the curriculum. The analysis of adult activities, then, was a method for determining those learning experiences that were most lifelike.

Social efficiency educators have tended to think that materials that most closely resemble adult activities in the home, the workplace, and in leisure time ought to be sought out and utilized in education. Traditional and perennialist educators have tended to find activities for students that move them to think and act like professional historians, mathematicians, scientists, writers, and the like. Progressive educators have tended to find problem-solving activities so that students might grow in the habit of analyzing and solving problems in their responsibilities as citizens and members of communities. In brief, socially efficient materials would aim at efficiency in the workplace and home, traditionalist materials would aim at developing early scientists or mathematicians, and progressive materials would aim at creating informed and pragmatic citizens.

Most recently, the educational philosopher Gary Fenstermacher has advocated studying adults in society to derive standards for curriculum in the schools. He claims that adults who have made a democratic society function have been characterized by four qualities: (1) reasonableness, (2) agency, (3) a sense of relationship, and (4) morality. Each of these, he says, must become a conscious aim of the curriculum. By reasonableness he means the ability to think clearly with the ability to pay attention to evidence and to connect evidence to claims about the world. By agency he means the ability to act on one's own plans and intentions and not solely on the plans and intentions of some other person or institution. By a sense of relationship Fenstermacher means a sense that other persons

are truly other and that relationships require a recognition of the legitimacy of that otherness. By morality he means cardinal virtues such as prudence, temperance, and courage.

Fenstermacher goes on to show that a liberal and progressive curriculum is required to meet those four aims and cites the work of Andre Comte-Sponville, Thomas Green, and Israel Scheffler as sources that support such achievement. The liberal education sponsored by this approach would combine the commitment to achieve the common good that is found in the work of orators such as Quintilian and John Dewey with the commitment to discover the truth that is found in philosophers such as Socrates and scientists such as Einstein.

### 17. How Far Shall Methods of Learning Be Standardized?

The editors of the *26th Yearbook* believed in the right of the individual student to learn what she or he needed to learn in the way that was most suited to that individual. Yet they also realized that there was a need to manage the curriculum so that student learning would not be lopsided. They thought that the weighting of material in the curriculum was primarily a responsibility of a centralized group of experts, and it was the responsibility of the school and the teachers to administer that curriculum. The accountability movement of the past 25 years has inspired the development of standards by subject matter organizations such as the National Council for Teachers of Mathematics and the National Council for the Social Studies for each of the areas of the curriculum. These national standards tend to be fairly general, but the mandate of the federal government has been to render them more specific through the generation of benchmarks and ultimately standardized test items through the agency of state and local boards of education. The tension between efforts to centralize curriculum standardization on the one hand and to rely upon the prudential professional judgment of teachers and school principals on the other has been very high at the beginning of the new century.

Any curriculum today needs to address the specific challenges arising from contemporary life. These challenges include the following: the increasing divide between the rich and poor, both

between and within nations; the mass displacement of peoples and families and the homelessness of millions; the mobility of student populations; the historically disproportionate number of single-parent families; religious, ethnic, gender, and racial conflicts; the rights of handicapped persons; and the dominance of computer and Internet technologies.

In the light of these challenges, Mortimer Adler and others have argued for one curriculum for all U.S. students from the perspective of traditional and humanistic education. They view this unity of curriculum as crucial to democracy and equality of opportunity in society. However, standardization of curriculum requires more uniformity than what these theorists would accept. With the possible exception of legislators, higher level governmental administrators, and single-minded advocates of educational accountability, it is difficult to find a curriculum thinker who advocates a highly standardized curriculum. For the most part, students of curriculum look at the complex set of challenges noted in the previous paragraph and acknowledge there must be a range of ways for curriculum to address them and an acknowledgment that no curriculum can address them all.

On the other hand, the mobility of children from one school to another argues for some level of standardization. In the 19th century, William Torrey Harris had developed a curriculum in St. Louis, Missouri, according to which if a student moved from one school on one day and into another the next he or she would not miss a beat, for all students would be on the same page in the same book. Harris's curriculum congers up an image of a standardized curriculum, which in the context of current technological prowess, shows promise for contemporary social sufficiency advocates. Whether or not the image is realistic is open to debate.

Perhaps the question is best understood through asking another question: What is learning? Is learning limited to exhibiting behaviors sought after by school administrators? If that is true, what could the philosopher of education Eugene A. Walsh have meant when he told students not to let school get in the way of their education? Curriculum scholar William Pinar has spent much of his career exploring the ramifications of *currere*, the Latin infinitive form of the verb *to run*. On this view,

one only understands learning in terms of the lived experience of individual persons and on how they report that experience and standardization if curriculum is in some respects irrelevant to learning. He and Walsh are probably on the same page and in fundamental agreement with the authors of volume 1 of the *107th Yearbook of the National Society for the Study of Education*.

### 18. What Are the Administrative Questions of Curriculum Making?

The editors of the *26th Yearbook* were part of the Progressive Era, and even when they disagreed about issues of the curriculum, they believed in the expertise of those who studied education as a science. Thus, they advocated at the same time a more centralized educational system and a more differentiated curriculum, both of which were to be managed by highly trained educational experts. This approach facilitated a divide between curriculum talk and actual curriculum practice, a divide which continues to this day.

In the first half of the 20th century there was a flurry of curriculum innovation including the project method of William Heard Kilpatrick, the Dalton plan of Helen Parkhurst, and the Eight Year Study of the Progressive Education Association. In the second half of the century, innovation continued with the disciplines of knowledge approach spawned by the National Defense Education Act (NDEA), a renewed focus on early childhood education supported by the Elementary and Secondary Education Act, and the accountability movement sanctioned by the Educate America Act of 1994. The accountability movement was renewed in the new century by the federal law NCLB.

A major difference between the innovations before mid-20th century and those after mid-century was the growing influence of the federal government on curriculum policy. Before NDEA, most curriculum reform was either endorsed by, supported by, or studied by some independent educational organization such as the National Education Association or the Progressive Education Association. The administrative progressives wanted curriculum to be in the hands of education experts who were independent of politics, but that independence has eroded gradually over the past

50 years. Especially since NCLB, the curriculum field has been floundering in a kind of no man's land. Curriculum scholars, subject area experts, teachers, school principals, social scientists, psychologists, and public intellectuals engage in what Tyack and Cuban call policy talk, while the actual curricular decisions are in the hands of politicians, and the implementation of those decisions are in the hands of standardized test and textbook publishers, computerized school management systems, and state and local board-of-education-level administrators. Some school districts have eliminated their curriculum departments to make sure there are sufficient funds for testing. The question "What knowledge is of most worth?" hardly seems relevant to actual school practice, and the range of contested curricular visions seems to these school districts as no longer important. Critical thought about curriculum is sought in theory, but scorned in practice.

So the administrative questions about curriculum are challenging indeed. A considerable amount of research has shown that when the school principal acts as an instructional leader the school improves significantly. Research on staff development, on the personal practical knowledge of teachers, on teachers' action research projects, on the formation of teachers into learning communities, and on consultancies and tuning protocols are examples of ways that principals have influenced curriculum effectively. School principals, however, need far more support from universities and from professional education organizations to redress the balance that has been lost since the middle of the 20th century.

The hope of an engaged curriculum movement in this country is to be found in trust in schools, trust in teachers, trust in administrators, trust in curriculum thinkers and researchers, and trust that politicians can be persuaded to pay as much attention to democracy and equality as a way of life; to research in neurobiology, educational anthropology, and arts education; and to the lived experience of teachers in schools as they currently do to test publishers and psychometricians.
